***Dedicated To
My Beloved Parents***

Declaration

I hereby declare that the whole work submitted as a thesis entitled "Effect of plant extracts on laboratory organisms and biodegrading agents found in the industrial effluent" to the Institute of Environmental Science, University of Rajshahi for the Degree Doctor of Philosophy is the result of my own investigation. The thesis contains no materials which have been accepted for the award of any other degree or diploma elsewhere except, where due reference is made in the text.

(RUKHSHANA SHALIM)
Candidate

Prof. Dr. Md. Nurul Islam

Department of Zoology, University of Rajshahi
Rajshahi 6205, Bangladesh

B.Sc. (Hons.) M.Sc. (RU), Ph.D (RU)

Telephone: 0721750097, +88 01715324366

E-mail: n_islamm@yahoo.com, nurulislam@ru.ac.bd

Certificate

*It is my pleasure to certify that the thesis entitled, “Effect of plant extracts on laboratory organisms and biodegrading agents found in the industrial effluent” submitted to the Institute of Environmental Science, University of Rajshahi by **Rukhshana Shalim** in partial fulfillment of the requirements for the degree of Doctor of Philosophy is a dissertation of the perfect study which she carried out in my laboratory with much success. It contains no materials previously published or written by any other person except, wherever, due references are made in the text of the thesis.*

I hereby clarify that the authoress completed her work mostly under my direct supervision and contributed some new ideas and openings in our research field by adding most recent information in this line of the contemporary world.

Acknowledgements

I would like to express my best regards, profound gratitude, indebtedness and deep appreciation to my honorable supervisor Dr. Md. Nurul Islam, Professor, Department of Zoology, University of Rajshahi, for his constant supervision, expert guidance, enthusiastic encouragement and never ending inspiration throughout the tenure of my research work, as well as for preparing this dissertation.

I also offer my special gratitude and heartfelt thanks to Dr. Md. Azizul Islam, honorable Director, Institute of Environmental Science, University of Rajshahi for his generous support and open hearted co-operation during the course of my research work.

I would also like to express my gratefulness to Professor Dr. Md. Sarwar Jahan; Dr. Md. Golam Mostofa, Dr. Md. Abul Kalam Azad, Dr. Md. Redwanur Rahman (Fellows/Associate Professors); Mrs. Zakia Yeasmin, S.M. Shafiuzzaman (Fellows/Assistant Professors), Institute of Environmental Science, University of Rajshahi for their immense help, kind cooperation and constructive advice during my research work. I would also like to give thanks to the office staffs of the Institute of Environmental Science, University of Rajshahi for their cordial assistance throughout the study period.

I am highly grateful to the Principal Md. Ekramul Alam of Bonpara Degree College, Natore, and Md. Sultan Ali, Secretary of the Institute of Environmental Science, University of Rajshahi for necessary help from their positions for a better completion of this work. I would like to extend my best thanks to Md. Shahadat Hossain (M.Phil.), Ronjon Kuamr Kund (M.Phil.), Md. Nazrul Islam (History), A.K.M. Ahasan Habib, Md. Nurul Islam, Md. Kumruzzman of Bonpara Degree College, Bonpara, Natore, Bangladesh for their continuous encouragement during the course of my research. I would also like to express my gratefulness to all my teachers of Department of Zoology, University of Rajshahi and to Prof. Dr. K. A. M. Shahadat Hossain Mondal of the Institute of Biological Sciences, University of Rajshahi for their kind help, valuable suggestions and constant inspiration during my research work.

It's my great pleasure to express my heartfelt thanks and best regards to Md. Badrul Islam, Md. Ruhul Amin and Md. Mozammel Hossain, Scientific Officers of the Bangladesh Council of Scientific and Industrial Research (BCSIR), Rajshahi for providing me additional laboratory facilities, as well as for their generous help, valuable suggestions to carry out the analytical part regarding the bacterial isolates found in the industrial effluent.

I express my regards to Dr. Md. Sarwar Jahan, Principal Scientific Officer, the Bangladesh Council of Scientific and Industrial Research (BCSIR) Laboratories, Dhaka, Bilkis Rukhsana, Assistant Conservator of Forest, Ministry of Forestry, Bangladesh and Mohammad Moniruzzaman, Senior Scientific Officer, BCSIR Laboratories, Dhaka for their encouragement for my higher study and research endeavor. I also express my regards to Dr. S.M. Abu Tauab Khandaker, Principal Scientific Officer, Soil Resource Development Institute, Rajshahi for his valuable suggestions.

I am extremely thankful to Dr. Md. Omor Ali Mondal, Muhammad Abdullah (Abdullah-1), Muhammad Moniruzzaman, Amit Kumar, Dr. Manjushree Chowdhury, Nayeema Parvin and Muhammad Md. Robiul Alam, who were around me with their goodwill and affection during my days in the Institute of Environmental Science, University of Rajshahi; and of-course very special thanks are due to Abdullah An Naser (Abdullah-2) and Fatema Ferdous Lopa without who's help this final touch would not have been accomplished.

I also express my heartfelt thanks to CDMP (Comprehensive Disaster Management Program) to contribute partial financial support to carry out this research project.

I am grateful to Md. Arshed Alam, Herbarium Keeper, Department of Botany, University of Rajshahi for helping me in identification and collection of the test plants for my research work. I am also thankful to Md. Zohurul Islam Babu for his sincere composing and printing the dissertation.

I also wish to express thanks to all my research colleagues, especially Dr. A K M Kamruzzaman, Muhammad Samser Ali Sumon, Md. Mizanur Rahman and A S M Shahidul Bari for their help and suggestions in need.

I am also grateful to Muhammad Shahin Alam, BSCIC (Bangladesh Small and Cottage Industries Corporation), Rajshahi who helped me collecting the plant materials, Rubena Begum, who help me processing the collected materials and Farhana Ferdous Oyshi for her valuable companion.

I also express my heartfelt thanks to all my friends and well-wishers especially to my friends Dr. Md. Shahidullah Pramanik, Dr. Md. Abu Masud, Md. Jahangir Alam, Nusrat Jahan Ruma and Tohura Khatun for their occasional help, wholehearted inspiration and mental support.

I am extremely grateful to all my family members, especially to my elder brother Md. Mashfiqur Rahman Rubel, my younger brothers Md. Mahmudur Rahman Rumon and Md. Mohibur Rahman Rupom and my son Md. Mahdeyur Rahman Polok, and my nieces Sanjida Rahman Juthe, Mahiat Rahman Jui and Tasnia Rahman Titly.

Finally, I owe my best regards to my beloved father Md. Mukhlesur Rahman (who breathed his last on 3rd February, whenever I have just started writing my thesis), my beloved mother Mrs. Aleya Rahman and my husband Md. Mostafizur Rahman Jewel for their moral support, constant encouragement and never ending affection and blessings.

June, 2014

Rukhshana Shalim

ABSTRACT

To determine whether or not the plant extracts affecting biodegrading agents that normalize industrial effluent sample plants known as bionomalizers *i.e.* *Carica papaya* Linn., *Moringa oliefera* Lam. and *Musa sapientum* L. were taken into consideration through dose mortality against the stored grain pest *Tribolium castaneum* (Hbst.), cytotoxicity against the brine shrimp *Artemia salina* nauplii and antibacterial activity against the 9 bacterial isolates from the tannery effluent and 7 certain other bacteria as laboratory test agents were done. Leaf, stem and roots of *C. papaya*; fruit, leaf, stem bark, stem wood, root bark and root wood of *M. oliefera*, and leaf, stem and roots of *Mu. sapientum* were extracted in petroleum ether, chloroform and methanol.

For *C. papaya* extracts against *T. castaneum* beetles the dose mortality was done through residual film assay to yield the highest and the lowest mortality for the CH₃OH extract of roots (LD₅₀ 0.114mg cm⁻²) and CHCl₃ extracts of stem (LD₅₀ 2.053mg cm⁻²) after 48h of exposure, while the CHCl₃ extracts of leaf and root didn't offer any mortality to the beetles. According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl₃ and CH₃OH extracts could be arranged in a descending order: root (CH₃OH) > stem (CH₃OH) > leaf (CH₃OH) > root (Pet.E.) > leaf (Pet.E.) > stem (Pet.E.) > stem (CHCl₃) extract. For *M. oliefera* the highest and the lowest mortality have been observed for the CH₃OH extract of root bark (LD₅₀ 0.276mg cm⁻²) and Pet.E. extract of root wood (LD₅₀ 0.629mg cm⁻²) after 48h of exposure. According to the intensity of activity observed through mortality of the adult beetles the potentiality of the Pet.E. and methanol extracts could be arranged in a descending order: root bark (CH₃OH) > stem bark (CH₃OH) > root bark (Pet.E.) > fruit (CH₃OH) > root wood (CH₃OH) > stem bark (Pet.E.) > stem wood (CH₃OH) > root wood (Pet.E.) extract. For *Mu. sapientum* the highest and the lowest mortality have been observed for the CH₃OH extract of stem (LD₅₀ 0.163mg cm⁻²) and Pet.E. extract of leaf (LD₅₀ 1.195mg cm⁻²) after 48h of exposure. According to the intensity of activity observed through

mortality of the adult beetles the potentiality of the extracts could be arranged in a descending order: stem (CH₃OH) > root (CH₃OH) > leaf (CH₃OH) > stem (Pet.E.) > root (Pet.E.) > leaf (Pet.E.) extract.

For *C. papaya* against the *A. salina* nauplii the highest and the lowest mortality have been observed for the CHCl₃ extract of leaf (LC₅₀ 1.326ppm) and CH₃OH extracts of leaf (LC₅₀ 183.443ppm) after 24h of exposure. According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl₃ and CH₃OH extracts could be arranged in a descending order: leaf (CHCl₃) > root (CH₃OH) > stem (CHCl₃) > stem (Pet.E.) > stem (CH₃OH) > root (CHCl₃) > root (Pet.E.) > leaf (Pet.E.) > leaf (CH₃OH) extract. For *M. oliefera* the highest and the lowest mortality have been observed from the CHCl₃ extract of root bark (LC₅₀ 4.197ppm) and CH₃OH extracts of fruit (LC₅₀ 234.246ppm) after 24h of exposure respectively. According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl₃ and CH₃OH extracts could be arranged in a descending order: root bark (CHCl₃) > root bark (CH₃OH) > stem wood (CHCl₃) > stem wood (CH₃OH) > root wood (CHCl₃) > stem wood (Pet.E.) > stem bark (CHCl₃) > fruit (Pet.E.) > root bark (Pet.E.) > fruit (CHCl₃) > root wood (Pet.E.) > fruit (CH₃OH) > stem bark (CH₃OH) > leaf (Pet.E.) > root wood (CH₃OH) > leaf (CH₃OH) extract. For *Mu. sapientum* the highest and the lowest mortality have been observed from the CH₃OH extract of leaf bark (LC₅₀ 22.991ppm) and Pet.E. extract of leaf (LC₅₀ 127.604ppm) after 24h of exposure. According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl₃ and CH₃OH extracts could be arranged in a descending order: leaf (CH₃OH) > leaf (CHCl₃) > stem (CHCl₃) > root (Pet.E.) > stem (Pet.E.) > root (CHCl₃) > root (CH₃OH) > stem (CH₃OH) > leaf (Pet.E.) extract.

Bacterial strains were isolated from tannery effluent. Fifteen colonies were screened from initial level of effluent on nutrient agar media. Out of fifteen colonies, nine isolates were selected for biochemical test and other studies. Selected isolates were: two isolates from sample 1 (isolate 1 and 2), four from sample 2 (isolate 3, 4, 5 and 6) and three from sample 3 (isolate 7, 8 and 9). The isolates were determined as

1. *Bacillus cereus*, 2. *Klebsiella oxytoca*, 3. *Staphylococcus aureus*, 4. *Escherichia coli* (I), 5. *Escherichia coli* (II) 6. *Citrobacter freundii*, 7. *Proteus vulgaris*, 8. *Bacillus subtilis*, 9. *Salmonella typhimurium*. Physico–chemical characteristics of the tannery effluent were also determined along with the characterization of the found bacterial isolates.

The Pet.E., CHCl₃ and CH₃OH extract of *C. papaya* (leaf, stem and root), *M. oleifera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) were tested against 7 selected bacteria (2 Gram positive bacteria *Bacillus subtilis*, *Staphylococcus aureus* and 5 Gram negative bacteria *Escherichia coli*, *Klebsiella pneumoniae*, *Salmonella enteritidis*, *Shigella flexneri* and *Shigella sonnei*) to evaluate their antibacterial potential at a concentration of 200 and 400µg disc⁻¹ along with a standard antibiotic, Ampicillin 10µg disc⁻¹ and 9 isolates (from industrial effluent) to evaluate their antibacterial potential at a concentration of 400µg disc⁻¹ along with a standard antibiotic, Kanamycin 30µg disc⁻¹.

Among the *C. papaya* extracts the root extracts showed the highest antibacterial activity. Only the *B. subtilis* (roots/CHCl₃ gave 20mm diam. for 400µg disc⁻¹), *K. pneumoniae* (stem/CHCl₃ gave 09mm in diam. for 400µg disc⁻¹) and *St. aureus* (leaf/Pet.E. gave 09mm in diam, stem/CHCl₃ gave 10mm in diam., roots/Pet.E. and CH₃OH gave 15mm and 10mm in diam. respectively, while all the tests were for 400µg disc⁻¹) were responsive among the selected test bacteria. Among the *M. oleifera* extracts the stem wood extracts showed the highest antibacterial activity. Only the (fruit/Pet.E. and stem bark/CHCl₃ both gave 09mm in diam. for 400µg disc⁻¹), *K. pneumoniae* (fruit and stem wood/CHCl₃ gave 11 and 10mm in diam. both for 400µg disc⁻¹) and *St. aureus* (fruit/Pet.E. and CHCl₃ gave 10mm and 09mm in diam., leaf/ Pet.E. gave 09mm in diam., and stem bark/Pet.E. and CH₃OH gave 09 and 10mm in diam. respectively, stem wood/Pet.E. and CH₃OH gave 10 and 12mm in diam. respectively, root bark/Pet.E. and CHCl₃ gave 11mm and 09mm in diam., and root wood/CHCl₃ gave 10mm in diam., while all the tests were for 400µg disc⁻¹) were responsive among the selected test bacteria. Among the *Mu. sapientum* extracts the root extracts showed the highest antibacterial activity. Only the *St. aureus* (stem and roots/Pet.E. gave 08mm and 10mm in diam., for 400µg disc⁻¹) were responsive among

the selected test bacteria. According to the susceptibility test bacteria could be arranged in a descending order of *St. aureus* > *B. subtilis* > *K. pneumoniae*.

The Pet.E., CHCl₃ and CH₃OH extract of *C. papaya* (leaf, stem and root), *M. oliefera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) were tested against 9 isolates viz. 1. *Bacillus cereus*, 2. *Klebsiella oxytoca*, 3. *Staphylococcus aureus*, 4. *Escherichia coli* (I), 5. *Escherichia coli* (II), (for the isolates 4 and 5 the strains were different but determination was not done) 6. *Citrobacter freundii*, 7. *Proteus vulgaris*, 8. *Bacillus subtilis*, 9. *Salmonella typhimurium*. Among the 9 Isolates Isolate 8 *B. subtilis* was highly responsive to the Pet.E. and CHCl₃ extracts of *C. papaya* stem (15 and 08mm), *M. oliefera* fruit (14 and 09mm) and root bark (10 and 16mm), and *Mu. sapientum* root (10 and 10mm) respectively; to the Pet.E. extracts of *C. papaya* root (11mm), *M. oliefera* root wood (11mm), *Mu. sapientum* stem (10mm), and to the CHCl₃ extract of *M. oliefera* stem bark (08mm). Next to the Isolate 8 it was Isolate 2 *K. oxytoca* responsive to the Pet.E. extract of *C. papaya* leaf (08mm), *M. oliefera* fruit (08mm), *Mu. sapientum* leaf (15mm) and root (10mm); and to the CHCl₃ extract of *C. papaya* leaf (08mm), *M. oliefera* stem bark (08mm), stem wood (08mm) and root bark (08mm); followed by the Isolate 1 *B. cereus* which was responsive to the Pet.E. extracts of *C. papaya* stem (16mm), *M. oliefera* fruit (10mm) and *Mu. sapientum* stem (8mm) and root (10mm); this was followed by Isolate 3 *St. aureus* which was responsive to the Pet.E. extracts of *C. papaya* stem (10mm), *M. oliefera* fruit (13mm) and *Mu. sapientum* root (08mm) and again the CHCl₃ extract of *M. oliefera* stem bark (08mm). This was followed by the Isolate 6 *Citrobacter freundii* where CHCl₃ extract of *C. papaya* stem (08mm) and Pet.E. extract of *Mu. sapientum* leaf (10mm) were found responsive. Isolate 4 *E. coli* (I) and 5 *E. coli* (II) (but different strains) and 9 *Sa. typhimurium* show response against Pet.E. extract of *C. papaya* stem (08mm), *M. oliefera* fruit (08mm) and CHCl₃ extract of *M. oliefera* stem wood (09mm) respectively. According to the susceptibility test bacteria could be arranged in a descending order of *B. subtilis* > *K. oxytoca* > *St. aureus* = *B. cereus* > *Citrobacter freundii* > *E. coli* (I) = *E. coli* (II) = *Sa. typhimurium*. Isolate 7 *P. vulgaris* was not responsive to any of the 12 extracts of the

3 test plants. For Kanamycin 30µg disc⁻¹ the inhibition zones for the Isolate 1, 2,3, 4, 5, 6, 7, 8 and 9 were 50, 35, 35, 40, 36, 42, 42, 55 and 40mm respectively. The differences of the clear zones given by Ampicillin 10µg disc⁻¹(tested against the 7 bacteria) and Kanamycin 30µg disc⁻¹ (tested against the 9 isolates) were nearly the same in majority of the test cases.

The bacterial isolates found in the industrial effluent, *i.e.* *B. subtilis*, *St. aureus*, one of the *E coli* strains, another species of *Klebsiella*, *K. oxytoca*, another species of *Salmonella*, *Sa. typhimurium* were among the list of available 7 test bacteria of the Institute of Environmental Science (IES), R.U. and the response in that separate experiments nearly resembles the results got against the 9 isolates carried out afterwards. However, *E coli* among the 7 didn't show any response at all. The activity of the Pet.E., CHCl₃ and CH₃OH extract of *C. papaya* (leaf, stem and root), *M. oliefera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) were mild in activity in general, and *P. vulgaris*, *Sa. typhimurium*, both *E. coli* and *Citrobacter freundii* didn't give any considerable clear zone. Thus, it could be mentioned that *C. papaya*, *M. oliefera* and *Mu. sapientum* plant materials are not so much effective against the biodegrading bacteria and obviously they are helpful in biodegradation of industrial effluents causing very insignificant harm to biodegrading bacteria.

Abbreviations OF THE SPECIAL WORDS USED IN THE TEXT

| | | | | | |
|--------------------|---|--------------------------------|------------------|---|--|
| # U | = | Number of insects used | i.e. | = | That is |
| h | = | Hour(s) | % kill | = | Insects killed per cent |
| Fig. | = | Figure | # Kill | = | Number of insects killed |
| CHCl ₃ | = | Chloroform | χ^2 | = | Chi-square |
| CH ₃ OH | = | Methanol | LC ₅₀ | = | Concentration required to kill 50% of test organisms |
| Pet.E. | = | Petroleum ether | LD ₅₀ | = | Dose required to kill 50% of test organisms |
| diam | = | Diameter | μg | = | Microgram |
| DMSO | = | Deuteromethyl sulphoxide | μl | = | Microliter |
| df | = | Degree of freedom | mg | = | Milligram(s) |
| Cr % | = | Corrected mortality percentage | ml | = | Milliliter |
| Emp Probit | = | Empirical Probit | mm | = | Milimeter |
| <i>et al.</i> , | = | And others (author) | cm ² | = | Centimeter square |
| Expt Probit | = | Expected Probit | Weight | = | Weighting coefficient |
| TSI | = | Triple Sugar Iron | ppm | = | Parts Per Million |

Chapter 1: Introduction

1.1. Background information on the title plants species

1.1.1. *Carica Papaya* Linn.

1.1.2. *Moringa oleifera* Lam.

1.1.3. *Musa sapientum* L.

1.2. Background information on the test organisms

1.2.1. *Tribolium castaneum* (Hbst.)

1.2.2. Brine shrimp (*A. salina*) nauplii

1.2.3. Agents for antimicrobial activity tests

1.3. Aims and Objectives of the research work

INTRODUCTION

1. General Introduction

A plant is a bioreactor, since functionally it's a synthetic laboratory that produces different biomolecules as metabolites. Common among these metabolites are compounds with protective action against insects, such as alkaloids, non-proteic amino acids, steroids, phenols, flavonoids, glycosids, glucosinolates, quinones, tannins and terpenoids. Since plants may contain hundreds or even thousands of metabolites, there is currently a resurgence of interest in the vegetable kingdom as a possible source of new lead compounds for introduction into the therapeutical screening programs (Hostettmann *et al.*, 1995).

Amongst the most promising of the natural products investigated to date are the metabolites. Although only about 10,000 secondary plant metabolites have been chemically identified, the total number of plant chemicals may exceed 400,000. There are a vast commucopia of defense chemicals, comprising repellents, feeding and oviposition deterrents, growth inhibitors, sterilants, toxicants, etc. (Champagne *et al.*, 1989). Plant derived materials or phytochemicals, which once formed the basis of pest control technology, are again being scrutinized for potentially useful products or as models for new classes of insecticides (Kubo and Nakanishi, 1978; Champagne *et al.*, 1989; Klocke, 1989; Nawrot and Harmatha, 1994).

Massive use of these insecticides has had a long and difficult road because the earliest data gathering done by researchers among farmers and natives revealed a lot of practices based on superstition, which, when tested by scientific methods were not shown to be effective. After the World War II few plant and plant extracts replaced synthetic insecticides that had shown promising effects, and were of widespread use. When synthetic insecticides appeared in the 1940's some people thought that botanical insecticides would disappear forever but problems like environmental contamination, residues in food and feed and pest resistance brought them back to the fore. There is no

doubt botanical insecticides are an interesting alternative to insect pest control, and on the other hand only a few of the more than 250,000 plant species on our planet have been properly evaluated for this purpose. Moreover, botanicals, because of their low-mammalian toxicity, have received much attention as control agents against pests. For example, in 1950, Heal *et al.* reported approximately 2,500 plants in 247 families with some sort of toxic property against insects. But to use them it is not enough that the plant be considered as promising or even with proven insecticidal properties. According to Feinstein (1952), over 2000 species of plants representing 170 odd families are said to have some insecticidal values. There are many species of plants of these families in Bangladesh that are used as traditional medicine by the native people from the remotest antiquity. There are a lot of publications with lists of plants with insecticidal properties.

Biodegradation is a natural phenomenon where certain microorganisms play a vital role in the degradation procedure, however not being acquainted with synthetic chemicals that are dumped in the regular wastes the degradation process is being hampered and thereby environmental pollution takes place. Within the past few decades the world advanced rapidly with remarkable development in all sectors of science and technology and still going through heavy industrialization and industry-based commerce. It is remarkable now the extent of pollution that took place in different parts of the biosphere due to presence of non-degradable residual agents in the synthetic raw materials that are used in different industries. So, a worldwide awareness has been created for the investigation of nature-friendly substances or such other essential agents to run the developmental works, as well as to investigate biodegrading agents to disintegrate the pollutants already being deposited in the environment.

Industrialization in Bangladesh is an increasing phenomenon since 1960s that opened ever-growing volumes of industrial effluents that result in the widespread pollution of water and soil areas of the country. Despite taking safety precautions these industrial wastes are released to the nature. It is very common that nature itself possesses an efficient system for the recovery of polluted areas by means of microorganisms capable of assimilating the hydrocarbons of oils and grease materials. However, the micro-flora of nature is no longer capable of effectively recovering thousand tons of industrial effluents finding every year their way into the environment. As a result, like other

countries the people of Bangladesh also have found themselves under the real threat of ecological disaster. Among the industrial effluents oils, oil derivatives, detergents and dye are the major part to play the key role in causing pollution. It is now necessary to consider non-hazardous components for the industries that might not hamper the biodegrading micro-organisms. Analysis of the development of biotechnologies relating to the recovery of polluted water and soil ecosystems and equipment enables one to come to the conclusion that the processes based on the byproduct biodegradation under the action of microorganisms are ecologically efficient.

The pollution of the environment with toxic heavy metals is spreading throughout the world along with industrial progress. Microorganisms and microbial products can be highly efficient bioaccumulations of soluble and particulate forms of metals especially dilute external solutions. Microbes related technologies may provide an alternative or addition to conventional method of metal removal or metal recovery (Selvi *et al.*, 2012). In the past few decades, uncontrolled urbanization has caused a serious pollution problem due to the disposal of sewage and industrial effluents to water bodies. Unlike many other pollutants, heavy metals are difficult to remove from the environment (Ren *et al.*, 2009). Microbes play massive role in the bio-geochemical cycling of toxic heavy metals and also in cleaning up or remediating metal-contaminated environments. Microorganisms have acquired a variety of mechanisms for adaptation to the presence of toxic heavy metals (Rajbanshi, 2008).

Tanning is one of the oldest industries in the world. During ancient times, tanning activities were organized to meet the local demands of leather footwear, drums and musical instruments. With the growth of population, the increasing requirement of leather and its products led to the establishment of large commercial tanneries. Tanneries are typically characterized as pollution intensive industrial complexes which generate widely varying, high-strength wastewaters. Tannery wastewaters are highly complex and characterized by high contents of organic, inorganic and nitrogenous compounds, chromium, sulfides, suspended solids and dissolved solids (Durai and Rajasimman, 2011). Biological treatment of wastewater is evaluated as a good treatment method for industrial effluents. Treatment of wastes with bacteria involves the stabilization of waste by decomposing them into harmless inorganic solids either by

aerobic or anaerobic process. Biological processes play a major role in the removal of contaminants and they take advantage of the astonishing catabolic versatility of microorganisms to either degrade or to convert such compounds.

Bacterial biomass can be used as an economical option for removing chromium from the effluent by reduction and bioaccumulation. Microorganisms are advantageous for metal detoxification as they are easy to grow, resulting in a rapid production of biomass, and are part of natural environment (Faryal *et al.*, 2007). It is therefore advantageous to develop a bioprocess utilizing selected indigenous microbes that are both Cr^{6+} resistant and Cr^{6+} reducing.

In the wake of industrialization, consequent urbanization and ever increasing population, the basic amenities of life viz. air, water and land are being polluted continuously (Chhikara and Dhankhar, 2008). Leather tanning is one of the main sectors in Bangladesh's leather industry. Large amounts of chrome powder and chrome liquor are used during tanning process. More than 1,70,000 tons of chromium wastes are discharged to the environment annually as a consequence of industrial manufacturing activities (Kamaludeen *et al.*, 2003). Due to its high oxidation potential, it can easily penetrate biological membranes and cause health hazards (Chaudhary *et al.*, 2003). Feeds and fertilizer production from tanned skin-cut wastes (SCW) is the most direct phenomenon of chromium eco-toxicity leading to food chain contamination in Bangladesh (Rafiqullah *et al.*, 2008). The SCW is protein-rich and indiscriminately used to produce poultry and fish feeds, and organic fertilizer. It is reported that feed ingredients produced from SCW contained chromium at levels as high as 2.49% (Hossain *et al.*, 2007).

In the early reviews many kinds of bacteria were found that they live in the industrial effluent, and many kinds of dyes and heavy metals are released there. Bacteria live there and dissolve them. Bacterial strains ZA-6, W-61, KS-2 and KS-14 were isolated from agricultural soil irrigated with tannery effluents and subsequently identified by 16S rDNA sequencing as *Stenotrophomonas maltophilia*, *Staphylococcus gallinarum*, *Pantoea* sp. and *Aeromonas* sp., respectively. All isolates were examined for their resistance to hexavalent chromium and other heavy metal ions. These results suggest that chromate resistance and reduction in these bacteria are related (Alam and Ahmad, 2012).

A chromium resistant bacterial strain KUCr1 (*Bacillus firmus*) exhibiting potential Cr(VI) reducing ability under in vitro aerobic condition is reported. The bacterial strain showed varied degree of resistance to different heavy metal (Sau *et al.*, 2008). The bacterial isolates (*Bacillus* sp. JDM-2-1 and *Staphylococcus capitis*) can be exploited for the bioremediation of hexavalent chromium containing wastes, since they seem to have a potential to reduce the toxic hexavalent form to its nontoxic trivalent form (Zahoor and Rehman, 2009). *Bacillus* sp. ev3 could reduce 91% of chromium from the medium after 96 h and was also capable to reduce 84% chromium from the industrial effluents after 144h (Rehman *et al.*, 2008). Hexavalent chromium reduction and accumulation by *Acinetobacter* AB1 isolated from Fez tanneries effluents were tested. This strain was able to resist to concentrations as high as 400mg L⁻¹ of Cr(VI) (Essahale *et al.*, 2012). Three bacterial strains were isolated from effluents of leather (CMBL Cr13, CMBL Cr14) and steel (CMBL Cr15) industries for their possible use in Cr(VI) detoxification of industrial waste. Cr(VI) reducing ability of the three strains ranged from 70 to 80% after 3 days of incubation. The possible use of these bacteria in environmental cleanup is discussed by Shakoori *et al.* (1999). The tested tannery effluents had extremely high levels of all the tested parameters indicating high pollution potential, dangerous effects on the receiving environments and creating many treatment difficulties. Treatment of the tannery effluent was a function of time and bacterial species *Pseudomonas stutzeri* considered the most, while *Bacillus* sp. considered the least efficient in the treatment of tannery wastewater (El-Bestawy, 2013).

The pollution of the environment with toxic heavy metals is spreading throughout the world along with industrial progress. Microorganisms and microbial products can be highly efficient bioaccumulations of soluble and particulate forms of metals especially dilute external solutions. The five isolates were selected based on high level of heavy metal and antibiotic resistances. On the basis of morphological, biochemical analysis revealed that, the isolates were authentically identified as *Escherichia coli*, *Bacillus* spp., *Pseudomonas* spp., *Flavobacterium* spp. and *Alcaligenes* spp. The identified isolates were resistant to zinc (Zn), copper (Cu), chromium (Cr), mercury (Hg) and lead (Pb). These identified heavy metal resistant bacteria could useful for the bioremediation of heavy metal contaminated tannery effluents (Selvi *et al.*, 2012). Chromate tolerant heterotrophs and coliforms found in tannery effluent (Verma *et al.*, 2001). A strain

CSCr-3 with high Cr(VI) reducing ability under alkaline conditions was isolated from a chromium landfill and identified as *Ochrobactrum* sp. on the basis of 16S rRNA gene sequence analysis. The cells were rod shaped, Gram-negative and motile (He *et al.*, 2009). Waste water containing chromium (Cr^{6+}) is by far the most important environmental challenge being faced. A total of 35 isolates have been selected as potential organism belonging to the species of *Moraxella* (14.3%), *Bacillus* (11.43%), *Streptococcus* (25.72%), *Staphylococcus* (5.7%), *Salmonella* (12.3%), *E. coli* (13.3%), *Enterobacter* (11.3%), *Hafnia alvei* (2.45%) and *Alcaligenes* (3.5%). The selected isolates were able to tolerate at least 500mg L^{-1} of Cr^{6+} (Fakruddin *et al.*, 2009). Cr(VI) is a toxic, soluble environmental contaminant. Some bacteria are able to reduce hexavalent chromium to the insoluble and less toxic Cr(III), and thus chromate bioremediation is of considerable interest. An indigenous chromium-reducing bacterial strain, Rb-2, isolated from a tannery water sample, was identified as *Ochrobactrum intermedium*. on the basis of 16S rRNA gene sequencing. This bacterial strain can be useful for Cr(VI) detoxification under a wide range of environmental conditions (Batool *et al.*, 2012; Maruf *et al.*, 2012). High salinity (1–10% w/v) of tannery wastewater makes it difficult to be treated by conventional biological treatment. Salt tolerant microbes can adapt to these saline conditions and degrade the organics in saline wastewater. Four salt tolerant bacterial strains isolated from marine and tannery saline wastewater samples were identified as *Pseudomonas aeruginosa*, *Bacillus flexus*, *Exiguobacterium homiense* and *Staphylococcus aureus* (Sivaprakasam *et al.*, 2008).

Leather, a traditional export item of Bangladesh, enjoys a good reputation worldwide for its quality. This sector plays a significant role in the economy of Bangladesh in terms of its contribution to export and domestic market (Sharif and Mainuddin, 2003). In Bangladesh, tanning or the process of making leather is mostly carried out in the South-Western region of Dhaka city, occupying 25 hectares of land at Hazaribagh, where about 90% of tannery industries of Bangladesh are located. Due to lack of appropriate waste management practices, both solid wastes and liquid effluents from these industries are deposited at different low-lying locations of Hazaribag without proper treatments (Zahid *et al.*, 2006). Components of these wastes include rotten flesh, fat, blood and skin, toxic chemicals, dissolved lime, chromium sulfate, alkali, hydrogen sulfide, sulfuric acid, bleach, dyes, oil, formic acid, heavy metals, suspended solids,

organic matters and so on (Bhuiyan *et al.*, 2011; Zahid *et al.*, 2006). Consequently, soil sediment, groundwater and surface water of nearby the river Buriganga and the Turag are polluted heavily through percolation of the leachate from these dumping sites (Zahid *et al.*, 2006). Despite the toxic chemical load, a number of bacterial species are found to be abundant in the microflora of tannery effluents (Lefebvre *et al.*, 2006; Tripathi *et al.*, 2011). While the details of the mechanism of resistance of this microflora to toxic chemicals are yet to be deciphered, three possible mechanisms are likely to operate separately or in combination: a) efflux systems can reduce toxic chemical loads b) toxic chemicals can be degraded or converted to less toxic forms; c) toxic chemicals can be sequestered into complex compounds or compartments (Maruf *et al.*, 2012). In accordance with known bio-technologies, the polluted medium may be exposed to the action of biological preparation; including microorganisms either in the form of pure isolated cultures or pools of microorganisms, that is to say a combination or association of two or more organisms. To accelerate the degradation some plant materials may be used keeping these pools functional, however it is important to observe whether the bio-normalizing plant materials destroy them or not.

Therefore, the present study was planned on the isolation and characterization of bacterial strains from the tannery effluent and compares their response in the test plant extracts. In this investigation plant extracts were also tested to evaluate their efficacy against the laboratory organisms, *i.e.*, *Tribolium castaneum* (Hbst.) a stored product pest and *Artemia salina* (L.), the recognisable agent for cytotoxicity test and some selected pathogenic bacteria to potentiate the extracts by evaluating the range of their effectiveness. Three plant species, *viz.* *Carica papaya* (Linn.), *Moringa oleifera* (Lam.) and *Musa sapientum* (L.) were used to yield a conclusion regarding their effect on laboratory organisms and on the biodegrading organisms found in the industrial effluent.

1.1. Background information on the title plant species

1.1.1. *Carica papaya* Linn.

C. papaya (family: Caricaceae) is a tropical tree which is native to the tropics of the Americas but now widely cultivated in other tropical regions of the world, for its edible melon-like fruit, which is available throughout the year (Banerjee *et al.*, 2006).

1.1.1.1. Origin and geographical distribution

Papaya is thought to have originated from Mexico and Central America. It was spread during the 16th century by the Spanish exploration from Central America to the Caribbean and the South East Asia. It is now widespread in the tropics in South America, Africa and Asia, and in the warm subtropics (Oceania) (Heuzé and Tran, 2012). It is grown worldwide in tropical and subtropical areas as a commercial crop, spreaded easily and become naturalized in many areas.

1.1.1.2. Systematic position

Kingdom: Plantae

Division: Magnoliophyta

Class: Magnoliopsida

Subclass: Dilleniidae

Order: Violales

Family: Caricacea

Genus: *Carica*

Species: *C. papaya* Linn.

Plate 1.1: *C. papaya* fruits on tree

The species includes perplexingly variable forms, sometimes classified as different varieties of species. It has several synonyms, *i.e.*, *C. pinnatifada* Heilborn, *C. cubensis* Solms-Laub., *C. portorricensis* Urban, *C. peltata* Hooker et Arnott, *Papaya hermaphrodita* Blanco, *C. edulis* Bojer, *C. mamaya* Vellozo, *C. sativa* Tuss., *Carica*

citriformis Jacq., *Papaya communis* Noroña, *Papaya cucumerina* Noroña, *Papaya papaya* (L.) Karsten, *Papaya vulgaris* A.DC.

The local names of the *C. papaya* are Fafay, Babaya in Arabic; Pappaiya, Papaya, Pepe (পেঁপেঁ) in Bengali; Thimbaw in Burmese; Pawpaw, Pawpaw tree, Melon tree, Papaya in English; Papaya, Lapaya, Kapaya in Filipino; Papailer, Papaye, Papayer in French; Papaya, Melonenbaum in German; Papaya, Papeeta in Hindi; Gedang, Papaya in Indonesian; Papaya, Betek, Ketalah, Kpaya in Malay; Pepol in Sinhala; Fruta bomba, Papaya, Papaita, Lechosa in Spanish; Pappali, pappayi in Tamil; Malakor, Loko in Thai; Du du in Vietnamese.

Plate 1.2: *C. papaya* trees

1.1.1.3. Morphological attributes

C. papaya tree is an erect, fast-growing tree measuring 7 to 8m tall, with copious latex and trunk of about 20cm in diameter (Duke, 1984). *C. papaya* plant has an erect branchless trunk and a palm like head of foliage at the top. The trunk remains somewhat succulent and soft wooded, and never develops true bark. The leaves are deeply incised and lobbed. Papaya is a very fast growing perennial herb. Male flowers are borne in clusters on stalks 90cm long; the flowers are funnel-shaped, about 2.5mm (0.1inch) long, and whitish, and the corolla is five-lobed, with 10 stamens in the throat. The female

flowers are considerably larger, on very short stalks, and often solitary in the leaf axils; they have five fleshy petals that are united toward the base and a large cylindrical or globose superior ovary that is crowned by five fan-shaped sessile stigmas. Most papaya trees bear male and female flowers on separate trees. There is no way of telling the sex until flowering. Some varieties are bisexual. Papaya is sensitive to salinity and frost, and does not tolerate water logging and flooding (Ecoport, 2009).

1.1.1.4. Common and folkloric uses of *C. papaya*

The fruits, leaves, and latex are used medicinally. Papain, a major compound in the fruit and latex has been used in brewing and wine making and the textile and tanning industries. It also has been reported that papaya leaf extract is used as a prophylaxis against malaria; Papain also is used to treat arthritis. The level of the compounds varies in the fruit, latex, leaves, and roots. Papain is also applied topically (in countries where it grows) for the treatment of cuts, rashes, stings and burns. Women in India, Bangladesh, Pakistan, Sri Lanka, and other countries have long used green papaya as a folk remedy for contraception and abortion.

Papaya is a common man's fruit; available throughout the year in the tropics. It is referred to as the "medicine tree" or "melon of health". Papaya is filled with nutrients (Jackwheeler, 2003). Plants which are used for medicinal purposes are generally cheap and are best sources of pharmacologically active substances and are good resistance to bacterial activity (Basile *et al.*, 1999). In general medicinal purposes, the plant is used tremendously. Whole *C. papaya*, *i.e.* its fruits, seeds, bark and leaves are used for treatment and curing many diseases. The edible portion of the fruit of *C. papaya* (pawpaw) contains both macro and micro minerals like Na, K, Ca, Mg, Fe, Cu, Zn and Mn (OECD, 2010). The plant is a source of carotenoides, vitamin C, thiamine, riboflavin, niacin, vitamin B₆ and vitamin K (Bari *et al.*, 2006; Adetuyi *et al.*, 2008; USDA, 2009). The seed had recently been linked to cure sickle cell diseases (Imaga, *et al.*, 2009), poisoning related renal disorder (Olagunju, *et al.*, 2009) and as an anti-helminthes (Okeniyi *et al.*, 2007).

Leaves contain large amounts of alkaloids, carpaine and pseudocarpine which creates positive effects on heart as well as on respiration (Perry and Metzger, 1980). The leaves of papaya have been shown to contain many active components that can increase the total antioxidant power in blood and reduce lipid peroxidation level, such as papain, chymopapain, cystatin, tocopherol, ascorbic acid, flavonoids, cyanogenic glucosides and glucosinolates. Leaf extract of *C. papaya* is well known as an anti-tumor agent (Walter Last, 2008). The papaya fruit, as well as all other parts of the plant, contain a milky juice in which an active principle known as papain is present. Aside from its value as a remedy in dyspepsia and kindred ailments, it has been utilized for the clarification of beer (Ayoola and Adeyeye, 2010).

It contains medicinal properties and the major active ingredients recorded *viz.* carpaine, chymopapain and papain, a bactericidal aglycone of glucotropaeolin, benzyl isothiocyanate, aglycoside sinigrin, theenzyme myrosin, and carpasemine (Akah *et al.*, 1997; Jackwheeler, 2003; Eno *et al.*, 2000; Wilson *et al.*, 2002; Seigler *et al.*, 2002). Papaya plants are also produced for papain and chymopapain, two industrially important proteolytic enzymes found in the milky white latex exuded by fruits. In general, female fruits tend to exude more papain than hermaphrodite fruits. Papaya contains antifertility properties, particularly the seeds, (Lohiya *et al.*, 1999). A complete loss of fertility has been reported in male rabbits, rats and monkey's fed an extract of papaya seeds (Glazer and Smith, 1971; Lohiya *et al.*, 1999; Pathak *et al.*, 2000).

1.1.2. *Moringa oleifera* Lam.

Moringa oleifera is the most widely cultivated species of monogeneric family, the Moringaceae. It commonly known as the Drumstick tree. *Moringa oleifera* is the best known of the thirteen species in the genus *Moringa*. These are *Moringa oleifera*, *M. arborea*, *M. borziana*, *M. concanensis*, *M. drouhardii*, *M. hildebrandtii*, *M. longituba*, *M. ovalifolia*, *M. peregrine*, *M. pygmaea*, *M. rivaie*, *M. ruspoliana* and *M. stenopetala* (Mahmood *et al.*, 2010).

1.1.2.1. Origin and geographical distribution

M. oleifera is indigenous to South Asia, where it grows in the Himalayan foothills from Northeastern Pakistan to Northern West Bengal, India (Sharma *et al.*, 2011). It has been introduced and become naturalized in other parts of India, Pakistan, Afghanistan, Bangladesh, Sri Lanka, Southeast Asia, West Asia, the Arabian Peninsula, East and West Africa, Southern Florida, throughout the West Indies, and from Mexico to Peru, Paraguay and Brazil. In Puerto Rico, it is grown chiefly as an ornamental and in fencerows and hedges and has become naturalized along roadsides on the coastal plains and lower foothills. The rapid growing tree was utilized by the ancient Romans, Greeks and Egyptians; it is now widely cultivated and has become naturalized in many locations in the tropics (Fahey, 2005; Sachan *et al.*, 2010).

1.1.2.2. Systematic position

Kingdom: Plantae

Division: Magnoliophyta

Class: Magnoliopsida

Subclass: Dilleniidae

Order: Capparales

Family: Moringaceae

Genus: *Moringa*

Species: *M. oleifera* Lam.

Plate 1.3: *M. oleifera* tree

The common name of *M. oleifera* are Drumstick tree, Horse radish tree, Mother's best friend, West Indian bean in English; Bean, Árbol del bean, Morango, Moringa in Spanish; Bèn ailé, Benzolive, Moringa in French; Sajina, (সজিনা, ছুড়ি) (Bangladesh). The local names of the *M. oleifera* are Rawag in Arabic; Dan-da-lun in Burmese; Malunggay in Filipino; Shajmah, Shajna, Segra in Hindi; Merunggai, Sajina in Malay;

Saijan, Sohanjna in Pakistan; Ma-rum in Thai; Shobhanjana in Sanskrit; Murangai, Murunga in Tamil.

1.1.2.3. Morphological attributes

Moringa is a slender softwood tree that branches freely and can be extremely fast growing. Although it can reach 3m heights in excess of 10m and a diameter of 20 to 40cm at chest height, it is generally considered a small to medium size tree (Radovich, 2009). The stem is normally straight but occasionally is poorly formed. The tree grows with a short, straight stem that reaches a height of 1.5 to 2m before it begins branching but can reach up to 3m (Foidl *et al.*, 2001). It has deep roots, and therefore it can survive in dry regions, and wide-open crown with a single stem. The extended branches grow in a disorganized manner and the canopy is umbrella shaped. Tripinnate compound leaves are feathery with green to dark green elliptical leaflets 1 to 2cm (0.4 to 0.8in) long. The tree is often mistaken for a legume because of its leaves. The alternate, twice or thrice pinnate leaves grow mostly at the branch tips. They are 20 to 70cm long, grayish-downy when young, long petiole with 8 to 10 pairs of pinnae each bearing two pairs of opposite, elliptic or obovate leaflets and one at the apex, 1 to 2cm long (Morton, 1991). Conspicuous, lightly fragrant flowers are borne on inflorescences 10 to 25cm (4 to 10in) long, and are generally white to cream colored, 2.5cm in diameter, borne in sprays, with 5 at the top of the flower, although they can be tinged with pink in some varieties. The flowers, which are pleasantly fragrant and 2.5cm wide are produced profusely in axillary, drooping panicles 10 to 25cm long (Sachan *et al.*, 2010). They are white or cream colored and yellow-dotted at the base. The five-reflexed sepals are linear-lanceolate. The five petals are slender-spatulate. They surround the five stamens and five staminodes and are reflexed except for the lowest. The fruits are trilobed capsules, and are frequently referred to as pods and fruits production in March and April.

1.1.2.4. Common and folkloric uses of *M. oleifera*

M. oleifera, commonly called the 'drumstick tree', is well known for its multi-purpose attributes, wide adaptability and ease of establishment. Its leaves, pods and flowers are

packed with nutrients, important both human and animals. *M. oleifera* possess highly therapeutic and pharmacological values, so its consumption in regular diet could possibly reduce the risk of degenerative diseases (Paliwal *et al.*, 2011c). *M. oleifera* is believed to possess numerous medical properties and is being used for the treatment of ascites, rheumatism (Anwar *et al.*, 2007), venomous bites (Mishra *et al.*, 2009), enhancing cardiac function (Limaye *et al.*, 1995), inflammation (Ezeamuzie *et al.*, 1996), liver disease (Rao and Misra, 1998), cancer, hematological, hepatic and renal function (Mazumder *et al.*, 1999). Almost all the parts of this plant: root, bark, gum, leaf, fruit (pods), flowers, seed and seed oil have been used for various ailments in the indigenous medicine of South Asia, including the treatment of inflammation and infectious diseases along with cardiovascular, gastrointestinal, hematological and hepatorenal disorders (Paliwal *et al.*, 2011b).

Moringa has been used in the traditional medicine passed down for centuries in many cultures around the world, for skin infections, anaemia, anxiety, asthma, blackheads, blood impurities, bronchitis, catarrh, chest congestion, cholera, conjunctivitis, cough, diarrhoea, eye and ear infections, fever, glandular, swelling, headaches, abnormal blood pressure, hysteria, pain in joints, pimples, psoriasis, respiratory disorders, scurvy, semen deficiency, sore throat, sprain, tuberculosis, for intestinal worms, lactation ,diabetes and pregnancy (Nikkon *et al.*, 2003). The healing properties of *Moringa* oil have been documented by ancient cultures.

Plate 1.4: *M. oleifera* flowers and fruits **

** (http://commons.wikimedia.org/wiki/File:Moringa_oleifera_sg.jpg)

It has tremendous cosmetic value and is used in body and hair care as a moisturizer and skin conditioner. It has been used also in skin preparations and ointments since Egyptian times (Ramachandran *et al.*, 1980; Sairam, 1999; Marcu, 2005).

It is vata and kapha suppressant. Due to its hot potency it is helpful in relieving from pain and also reduces inflammation. It is also helpful in curbing the infection in the body. It is very much effective in stimulating the nervous system. Due to pungent taste it is effective in treating the digestive disorders, worm infestation, and constipation. It stimulates heart and also increases the blood density because of its hot potency. It is also a good antitussive and helps in resolving from extra mucus in the respiratory tract because of its bitter nature. Due to hot potency it is helpful in maintaining the proper menstrual cycle. It is also helpful in relieving from skin related problems as it generates sweat in the body.

Its bark, roots, fruit, flowers, leaves, seeds, and gum are also used medicinally. Uses include as an antiseptic and in treating rheumatism, snake bites, and other conditions. Boiled leaves used to help increase lactation. Juice of the root with milk used for asthma, hiccups, gout, lumbago. In West Bengal, India, roots taken by women, especially prostitutes, for permanent contraception. The seed is often used to purify dirty or cloudy drinking water. In the Nile Valley, the name of the tree is `Shagara al Rauwaq` which means `tree for purifying` (Von Maydell, 1986).

M. oleifera is an anti-pyretic (Fahey, 2005; Fisher, 2011), anti-inflammatory (Hukkeri *et al.*, 2006; Holst, 2000; Sing and Kumar, 1999), and possesses a broad spectrum of anti-bacterial, anti-fungal, anti-viral and antibiotic abilities, which may certainly lighten the load on the immune system (Caceres *et al.*, 1992; Ezeamuzie *et al.*, 1996). A *Moringa* dietary protocol makes perfect sense to combat the ravages of Lyme disease (Kjaer *et al.*, 1979; Kurup and Narasimha, 1954; Viera *et al.*, 2010; Eilert *et al.*, 1981; Jahn *et al.*, 1986; Das *et al.*, 1957; Bennett *et al.*, 2003; Fahey *et al.*, 2001). According to Fuglie (1999) the many uses for *Moringa* include: alley cropping (biomass production), animal forage (leaves and treated seed-cake), biogas (from leaves), domestic cleaning agent (crushed leaves), blue dye (wood), fencing (living trees), fertilizer (seed-cake), foliar nutrient (juice expressed from the leaves), green manure (from leaves), gum (from tree

trunks), honey and sugar cane juice-clarifier (powdered seeds), honey (flower nectar), medicine (all plant parts), ornamental plantings, biopesticide (soil incorporation of leaves to prevent seedling damping off), pulp (wood), rope (bark), tannin for tanning hides (bark and gum), water purification (powdered seeds) (Adebayo *et al.*, 2011). Various parts of this plant such as the leaves, roots, seed, bark, fruit, flowers and immature pods act as cardiac and circulatory stimulants, possess antitumor, antipyretic, antiepileptic, anti-inflammatory (Kumar *et al.*, 2009), antiulcer, antispasmodic, diuretic, antihypertensive, cholesterol lowering, antioxidant, antidiabetic, hepatoprotective, antibacterial and antifungal activities and are being employed for the treatment of different ailments in the indigenous system of medicine, particularly in South Asia (Anwar and Rashid, 2007; Anwar and Bhangar, 2003; Fakurazi *et al.*, 2008; Paliwal *et al.*, 2011a). It is generally known in the developing world as a vegetable, a medicinal plant and a source of vegetable oil (Bennett *et al.*, 2003; Paliwal *et al.*, 2011b).

1.1.3. *Musa sapientum* L.

Musa sapientum which is commonly called banana is a herbaceous plant of the family Musaceae. Akinyosoye (1991) reported that the plant is cultivated primarily for its fruits and to a lesser extent for the production of fibre. It is also believed to be an ornamental plant.

1.1.3.1. Origin and geographical distribution

In different countries about 300 varieties of bananas are grown, of which a vast majority have been growing in Asian, Indo- Malaysian and Australian tropics and are now widely found throughout the tropical and subtropical countries. India, Philippines, China, Ecuador, Brazil, Indonesia, Mexico, Costa Rica, Colombia, Thailand are the top banana producing countries. It is extensively grown and cultivated as a fruit plant all over Bangladesh.

The banana grows almost everywhere in the country throughout the year. The principal banana growing areas however, are Rangamati, Barisal, Rangpur, Dinajpur, Noakhali, Faridpur and Khulna (Rahman and Kabir, 2003).

1.1.3.2. Systematic position

Kingdom: Plantae

Division: Magnoliophyta

Class: Liliopsida

Subclass: Zingiberidae

Order: Zingiberales

Family: Musaceae

Genus: *Musa*

Species: *M. sapientum* L.

The local names of *Mu. sapientum* are Kala (কলা) in Bengali; Tawngyet byaw in Burmese; Dessert banana, Banana in English; Banane cultivée, Bananier des in French; Adamsfeige, Dessert banane in German; Banana in Japanese; Biu, Cau in Malay; Banana, Bananeira in Spanish; Vaazhai in Tamil.

Plate 1.5: *Mu. sapientum* tree

1.1.3.3. Morphological attributes

Mu. sapientum is the largest herbaceous flowering plant. Plants are normally tall and fairly sturdy and are often mistaken for trees, but their main or upright stem is actually a pseudostem that grows 6 to 7.6m tall, growing from a corm. Each pseudostem can produce a single bunch of bananas. After fruiting, the pseudostem dies, but offshoots may develop from the base of the plant. Leaves are spirally arranged and may grow 2.7m long and 60cm wide. They are easily torn by the wind, resulting in the familiar frond look. Each pseudostem normally produces a single inflorescence, also known as the *banana heart*. The inflorescence contains many bracts (sometimes incorrectly called petals) between rows of flowers.

1.1.3.4. Common and folkloric uses of *Mu. sapientum*

Medicinal plants are frequently used in traditional medicine to treat different diseases in different areas of the world (Palombo, 2005). This indigenous knowledge, passed down from generation to generation, has significantly contributed to the development of different traditional systems of medicine (Jachak and Saklani, 2007), as well as helped in exploration of different medicinal plants to find the scientific basis of their traditional uses.

Young leaves of *Mu. sapientum* used for cool dressing of inflamed and blistered surfaces and as cool application for headaches. The trunk juice is applied to scalp for thinning hair. Cooked flower used for diabetes in India. Sap of the flower is used for ear-aches. In South-Western Nigeria, green fruits used for diabetes. The fruit of *Mu. paradisiaca* and *Mu. sapientum* is traditionally used in diarrhoea (unripe), dysentery, intestinal lesions in ulcerative colitis, diabetes (unripe), in sprue, uremia, nephritis, gout, hypertension, cardiac disease (Ghani, 2003; Khare, 2007). *M. sapientum* is also used in the treatment of excess menstruation with *Canna indica* L. var. *speciosa* (Partha and Hossain, 2007). Banana leaves (ashes) are used in eczema (Okoli, 2007), as cool dressings for blister and burns (Ghani, 2003). Stem juice of fruited plant is used for treating diarrhoea, dysentery, cholera, otalgia, haemoptysis and flower is used in dysentery, diabetes and menorrhagia (Ghani, 2003). The root is used as anthelmintic (Khare, 2007), blood disorders, venereal diseases (Ghani, 2003). The plant is also used in inflammation, pain and snakebite (Coe and Anderson, 1999).

Various researchers evaluated *Mu. sapientum* for its antidiarrhoeal activity (Block, 1941; Emery *et al.*, 1997; Rabbani *et al.*, 1999, 2001; Malik, *et al.*, 1991), antiulcerogenic (Goel *et al.*, 1985; Lewis *et al.*, 1999), hypoglycemic activity (Ojewole and Adewunmi, 2003; Rai *et al.*, 2009; Usha *et al.*, 1989; Singh *et al.*, 2007; Gomathy *et al.*, 1990), antidiabetic (Pari and Maheswari, 1999; Usha *et al.*, 1991), antitumoral and antimutagenic (Lohsoonthorn and Danvivat, 1995; Deneo-Pellegrini *et al.*, 1996; Murakami *et al.*, 1998; Botting *et al.*, 1999), antioxidant activity (Yin *et al.*, 2008; Mokbel and Hashinaga,

2005; Vijayakumar *et al.* 2008), diuretic activity (Jain *et al.*, 2007; Rizvi *et al.*, 2011; Sood *et al.*, 1985; Chodera *et al.*, 1991), wound healing activity (Agarwal *et al.* 2009), anti-allergic activity (Tewtrakul *et al.*, 2008) and have been also found to be effective in treatment of migraine (Guariso *et al.*, 1993) and hypertension (Osim *et al.* 1990; Perfumi *et al.* 1994; Orie, 1997; Sarkar *et al.*, 1999) antioxidant (Pari and Maheswari, 2000).

1.2. Background information on the test organisms

The whole project has been designed to carry on screening of the crude extracts of the test plant species on several test organisms for the detection of their biological activities by analyzing the data statistically that read on various parameters during the course of the work. The following test steps have been taken into consideration:

1.2.1. *Tribolium castaneum* (Hbst.)

The red flour beetle is Indo-Australian origin and is found in temperate region, but will survive the winter in protected places, especially where there is central heat (Tripathi *et al.*, 2001). In the United States, it is found primarily in the southern states. *T. castaneum* is a worldwide and commonest stored pest of wheat-flour. It is commonly known as 'Rust-red flour beetle'. It is an insect of the family Tenebrionidae under the order Coleoptera. It is one of the serious pests of stored products. Mouth-parts of this pest insect are not adapted to feed on hard whole grains and they are thus found in almost any kind of flour, cracked grains etc. The specific food of *T. castaneum*, which includes whole-wheat flour, bran, rice flour, cornmeal, barley flour and oatmeal. It also feeds upon dried fruits, dried plant roots, nuts, chocolates, drugs, snuff, cayenne pepper, pulses and prepared cereal foods such as corn flakes (Metcalf and Flint, 1962). Not only pulses and millets, but cereals are also been attacked by this beetle (Purthi and Singh, 1950). *T. castaneum*, attack meal, crackers, beans, spices, pasta, cake mix, dried pet food, dried flowers and even dried museum specimens (Via, 1999; Weston and Rattlingroud, 2000). Although small beetles, about ¼ of an inch long, the adults are long-lived and may live for more than three years. The red flour beetle is reddish-brown in color and its antennae end in a three-segmented club (Bousquet, 1990).

Table 1.1: Developmental rates of *T. castaneum*

| Rearing Temperature | 30°C | 34°C |
|----------------------------|-------------|-------------|
| Egg | 3 days | 2 days |
| Larva | 20 days | 15 days |
| Pupa | 4 days | 3 days |
| Reproductive Maturation | 5 days | 4 days |
| Total time egg to egg | 32 days | 24 days |

The eggs are white, microscopic and often have bits of flour stuck to their surface. The slender larvae are creamy yellow to light brown in color. They have two dark pointed projections on the last body segment. The young larva is yellowish white and measures 1 mm in length. As it matures, it turns reddish yellow, becomes hairy and measures over 6 mm in length. Its head, appendages and the last abdominal segment are darker. The adult is a small reddish-brown beetle, measuring about 3.5mm in length and 1.2 mm in width. Its antennae are bent and bear a distinct club formed by the three enlarged terminal joints. The last antennal segment is transversely rounded. It was commonly found in the wild state in rotting wood and in loose bark of trees in India. This insect is now widely distributed all over the world mainly through commerce. The red flour beetle may be present in large numbers in infested grain, but are unable to attack sound or undamaged grain. Both the larva and adults cause damage. They are found in great numbers on infested materials and caused serious losses and considerable damage to flour and grains that have previously been attacked by other pests. Much of the damage done by *T. castaneum* is directly to kernels (germ and endoplasm). In case of severe infestation flour or other materials invaded may have a characteristics pungent odor as a result of the gaseous secretion exuded by the beetle. Such flour has an exceedingly low viscosity and its elasticity is markedly affected, which may cause gastric disturbance if used as food. In

severe infestation, the flour turn grayish and moldy and has a pungent, disagreeable odor making it unfit for human consumption (Good, 1936).

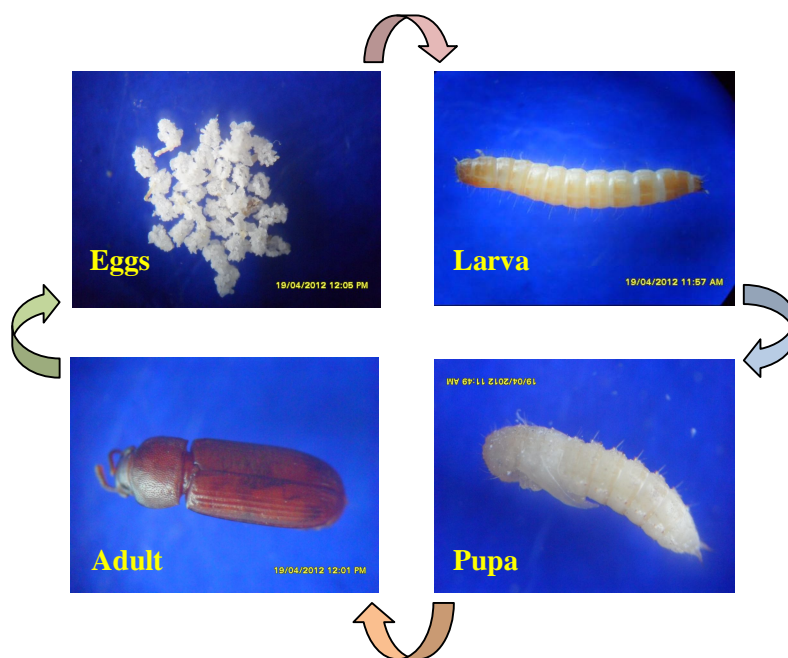

Plate 1.6: Life cycle of *T. castaneum*

Infested material will show many elongate reddish brown beetles, about 1/7 inch long crawling over the material when it is disturbed and brownish white (somewhat flattened) six-legged larval bedding on the inside of the grain kernels and crawling over the infested seeds. They are generally known among millers as “bran bugs”. *T. castaneum* contaminates more than they consume.

According to Khan (1981) this contamination results from;

- the presence of living or dead insects or insect parts;
- cast exuviae, egg shell and pupal cases;
- fecal and persistent odour; and
- webbing of food.

Tribolium species are major pests of stored grains and grain products in the tropics. Control of these insects relies heavily on the use of synthetic insecticides and fumigants, which has led to problems such as disturbances of the environment, increasing costs of application, pest resurgence, pest resistance to pesticides and lethal effects on non-target organisms in addition to direct toxicity to users (Jembere *et al.*, 1995). Thus, repellents, fumigants, feeding deterrents and insecticides of natural origin are rational alternatives to synthetic insecticides.

1.2.2. *Artemia salina* (Brine shrimp) nauplii

Brine shrimp lethality bioassay is a recent development in the bioassay for the bioactive compounds, which indicates cytotoxicity, as well as, a wide range of pharmacological activities (e.g. anticancer, antiviral, pesticidal, anti-AIDS, etc.) of the compounds. Bioactive compounds are almost always toxic in high doses. Pharmacology is simply toxicology at a lower dose or toxicology is simply pharmacology at a higher dose. Brine shrimp lethality bioassay is a bench top bioassay method for evaluating anticancer, anti-microbial and pharmacological activities of natural products. Natural product extracts, fractions or pure compounds can be tested for their bioactivity by this method.

Here *in vivo* lethality of a simple zoological organism (brine shrimp nauplii; Plate 1.6) is used as a convenient monitor for screening a fractionation in the discovery of new bioactive natural products. Generally, the median effective dose (ED₅₀) values for cytotoxicity are one tenth (1/10) of median lethal dose (LC₅₀) values in the brine shrimp test.

Plate 1.7: *A. salina* nauplius

The *A. salina* belongs to a genus of very primordial crustacean (crawfish - crayfish) the *Anostraca* (Fairy Shrimps). Crawfish of this genus just have a divided exoskeleton made of Chitin enhanced protein, no usual crust of chitin (escutcheon) as other crawfish have. There are many species within the genus of *Anostraca*, but the *A. salina* are very nice to grow, since the rate of successful hatches is very high. To carry on toxicity tests of certain materials these nauplii are very easy to grow from its marketed cysts and to set experiments thereby.

1.2.3. Agents for antimicrobial activity tests

The combination of the genetic versatility of microbes and the widespread overuse of antibiotics has led to increasing clinical resistance of previously sensitive microorganisms and the emergence of previously uncommon infections.

The principle of antimicrobial testing of plant extracts is based on the observation of the growth reduction of microorganisms after contact with plant tissues of extracts to be tested. So, it is very important to determine whether the crude extracts are active against various types of test organisms or not and thus a preliminary antibacterial screening of the crude extract was very much necessary. Therefore, screening was done against various pathogenic bacteria by disc diffusion assay method. The bacterial strains were cultured and used in the experiments carried out at the Microbiology Laboratory of the Institute of Environmental Sciences, University of Rajshahi, Rajshahi-6205, Bangladesh. Among the collected strains *Escherichia coli*, *Klebsiella pneumoniae*, *Salmonella enteritidis*, *Shigella flexneri*, *Shigella sonnei* were Gram negative and *Bacillus subtilis*, *Staphylococcus aureus* were Gram positive bacteria.

1.2.3.1. List of the test pathogenic bacteria

Table 1.2: List of the test pathogenic bacteria and their pathogenicity.

| Gram-negative Bacteria | | |
|------------------------|-------------------------------|---|
| Sl. No. | Bacteria | Pathogenicity |
| 1. | <i>Escherichia coli</i> | Most <i>E. coli</i> strains are harmless, but some serotypes are pathogenic and can cause serious food poisoning in humans, and are occasionally responsible for product recalls gastroenteritis, urinary tract infections, and neonatal meningitis. In rare cases, virulent strains are also responsible for haemolytic-uremic syndrome, peritonitis, mastitis, septicaemia and Gram-negative pneumonia. |
| 2. | <i>Klebsiella pneumoniae</i> | <i>K. pneumoniae</i> is a Gram-negative, non-motile, encapsulated, lactose-fermenting, facultative anaerobic, rod-shaped bacterium. Although found in the normal flora of the mouth, skin, and intestines (Ryan <i>et al.</i> , 2004). It can cause destructive changes to human lungs if aspirated. |
| 3. | <i>Salmonella enteritidis</i> | Most cases of salmonellosis are caused by food infected with <i>S. enteric</i> . Secreted proteins are of major importance for the pathogenesis of infectious diseases caused by <i>Salmonella enteritidis</i> . A remarkable large number of fimbrial and non-fimbrial adhesins are present in <i>Salmonella</i> , and mediate biofilm formation and contact to host cells. Secreted proteins are also involved in host cell invasion and intracellular proliferation, two hallmarks of <i>Salmonella</i> pathogenesis (Gerlach <i>et al.</i> , 2009). |

| | |
|-----------------------------|---|
| 4. <i>Shigella flexneri</i> | In humans and other primates, <i>Shigella flexneri</i> is responsible for causing an acute bloody diarrhea known as shigellosis or bacillary dysentery (Jin <i>et al.</i> 2002). Aside from bloody diarrhea, other symptoms include fever and stomach cramps. The bleeding is due to destruction of the intestines. The bacteria destroy the intestinal epithelium, then continue to break down the intestinal mucosa in the cecum and rectum (Clark and Maurelli, 2007). |
| 5. <i>Shigella sonnei</i> | <i>Shigella sonnei</i> is a species of <i>Shigella</i> . Together with <i>Shigella flexneri</i> , it is responsible for 90% of shigellosis (Mims <i>et al.</i> , 1993). |

Gram-positive Bacteria

| | |
|---------------------------------|--|
| 6. <i>Bacillus subtilis</i> | <i>B. subtilis</i> is only known to cause disease in severely immunocompromised patients, and can conversely be used as a probiotic in healthy individuals. It rarely causes food poisoning (Ryan <i>et al.</i> , 2004). |
| 7. <i>Staphylococcus aureus</i> | Wound infection, abscesses, endocarditis, septicaemia, osteomyelitis and food poisoning. |

1.3. Aims and objectives of the research work

Quite a good number of plants have been identified and utilized for insecticidal and medicinal purpose till to date. But it is true that a large number of plants have still been untouched or less investigated from which significant results can be obtained to control the pest of crops and disease problems of human beings. *C. papaya*, *M. oleifera* and *Mu. sapientum* are such plants that have been studied phytochemically and studies have been done only on its medicinal properties, but in details works done till to date on its use

for the control of crop pests', as well as its function on biodegrading agents are scanty. Accordingly, a research topic entitled "Effect of plant extracts on laboratory organisms and biodegrading agents found in the industrial effluent" has been taken into consideration.

Objectives of this work

1. To trace presence of bioactive potentials in *C. papaya*, *M. oleifera* and *Mu. sapientum* through primary screening:
 - by using the stored product pest *T. castaneum* to evaluate insecticidal effect of the extracts through dose-mortality assays by establishing LD₅₀ values;
 - by using *A. salina*, the recognized test agent for cytotoxic effect of the extracts by establishing LC₅₀ values;
 - by using human pathogenic bacteria to detect antibacterial activity;
2. Component analysis of the collected effluent.
3. Detection and identification of biodegrading agents (microorganisms) from industrial effluent.
4. Laboratory culture of the identified bacterial isolates and evaluation of plant extracts' impact on them.
5. To standardize the essences of the test materials through searching literature and web information in comparison with the results of the investigation to be carried out on their possible use in the contemporary pest control technology.
6. To comment on the future perspectives of the test plants depending on the achieved results.

Chapter 2: Materials and Methods

- 2.1. Selection of plant materials
- 2.2. Bioassays for activity of the collected extracts
- 2.3. Bioassay through surface film method
- 2.4. Bioassay through lethality test
- 2.5. Selection of microorganisms for antibacterial test agents
- 2.6. Isolation and Identification of bacteria from industrial effluent

Chapter 2

Materials & Methods

After development of multimedia techniques natural resources have been used to be the potential source for safe, biodegradable and more beneficial drugs, remedies or pesticides for a sustainable environment on the planet. Insects, mites, algae, or even micro-organisms have also been subjected to yield active compound in this regard. But plants are the most suitable source for such an interesting propagation in the field of pesticide technology while some plants in different parts of the world are considered toxic and some are used in the traditional medicine. Literature search on the title plants offered some essential openings on these species bears repellent, and toxicological properties which were subjected by different researchers to go thorough screening with a view to develop natural non-hazardous biodegradable pesticides, bionormalizers, etc.

2.1. Selection of plant materials

In order to arrive at useful compounds in the shortest possible time, careful selection of plant material is obviously very important. Random collection is one method but it is more judicious to base the selection on certain criteria. By way of illustration, plants used in traditional medicine are more likely to provide pharmacologically active compounds (Huxtable, 1992). Similarly, folk use of toxic plants could be taken with desirable output. In case of very small plants, such as herbs, shrubs, grass, etc. normally the whole plant is subjected for extraction, because the distribution of constituents generally not vary too much. Being a large timber plant, the distribution of compounds in different parts of this plant is obviously different. The presence of constituents in the heart-wood may disappear in the leaves; similarly constituents in the roots may not be the same that present there in the fruits.

In this proposition different parts of the test plants, (i) *C. papaya* leaves, stems and roots; (ii) *M. oleifera* leaves, fruits, stem bark, stem wood, root bark, root wood, and (iii) *Mu. sapientum* leaves, stem and root have been collected for the detection of

toxic properties and bio-active constituents since the plants are well known as medicinal plants.

2.1.1. Preparation of plant materials for extraction

The fresh materials of *C. papaya*, *M. oleifera* and *Mu. sapientum* were collected from the campus of the University of Rajshahi and adjacent areas in the following way:

***C. papaya*:** After collection leaves and stem were cut into small pieces; roots were collected by digging up without damaging them and excess soil were removed without washing and cut into small pieces as thin as possible and spread out to dry without heaping the material together. It was done under the shade avoiding direct sunshine.

Plate 2.1: Chopped parts of *M. oleifera*

***M. oleifera*:** After collection the leaves were spread out to dry without heaping; fruits were picked up and cut into small pieces; after collection the stem bark and stem wood were separated from the stem and cut into small pieces as thin as possible. Roots were collected by digging up without damaging them and shake and brush away excess soil without washing. The root bark was collected by stripping out from

the root and after removal of the root bark the root wood was collected and cut into small pieces as thin as possible. Then the plant parts were dried thoroughly in a well-ventilated place.

***Mu. sapientum*:** After collection leaves and stem were cut into small pieces; roots were collected by digging up without damaging and brush away excess soil without washing and cut into small pieces as thin as possible and spread out to dry.

2.1.2. Chemical extraction of the collected materials

There are basically two methods for extracting compounds from plant materials. Which one to choose, depends on whether the aim is to extract the more polar compounds (especially glycosides) which are present in the cell vacuole, or to obtain the less polar aglycones present on the surface of the plant, in aerial parts, heartwood or roots. In the present study three solvents petroleum ether (Pet.E.), chloroform (CHCl_3) and methanol (CH_3OH) were selected to extract for different parts of *C. papaya*, *M. oleifera* and *Mu. sapientum* separately.

All the plant materials were individually powdered in a grinder machine avoiding excess heat during grinding. The powdered materials, viz. leaves, stem and root of *C. Papaya*; leaves, fruits, stem bark, stem wood, root bark and root wood of *M. Oleifera*; leaves, stem and root of *Mu. sapientum* were weighed and placed in separate conical flasks to add sufficient amount of solvents maintaining a minimum ratio of 1:3 (1g dust: 3ml solvent). Then the conical flasks were put on an orbital shaker (Plate 2.2) for 48h and filtered (Plate 2.3) using 90mm Whatman filter paper. This was repeated for three times. Then the conical flasks were left open for evaporation for 24 to 48h before adding the next solvent.

The extraction was firstly done by the Pet.E. solvent followed by CHCl_3 and CH_3OH . Extracts, thus obtained were concentrated on a rotary evaporator at 40°C and only as residues (extracts) left were collected in to glass vials and preserved in a refrigerator at 4°C with proper labeling (Plate 2.4). For each of the samples three solvents have been used separately and successively.

Plate 2.2: Shaking on the shaker

Plate 2.3: Filtration of extracts

Plate 2.4: Extracts in vials with proper labeling

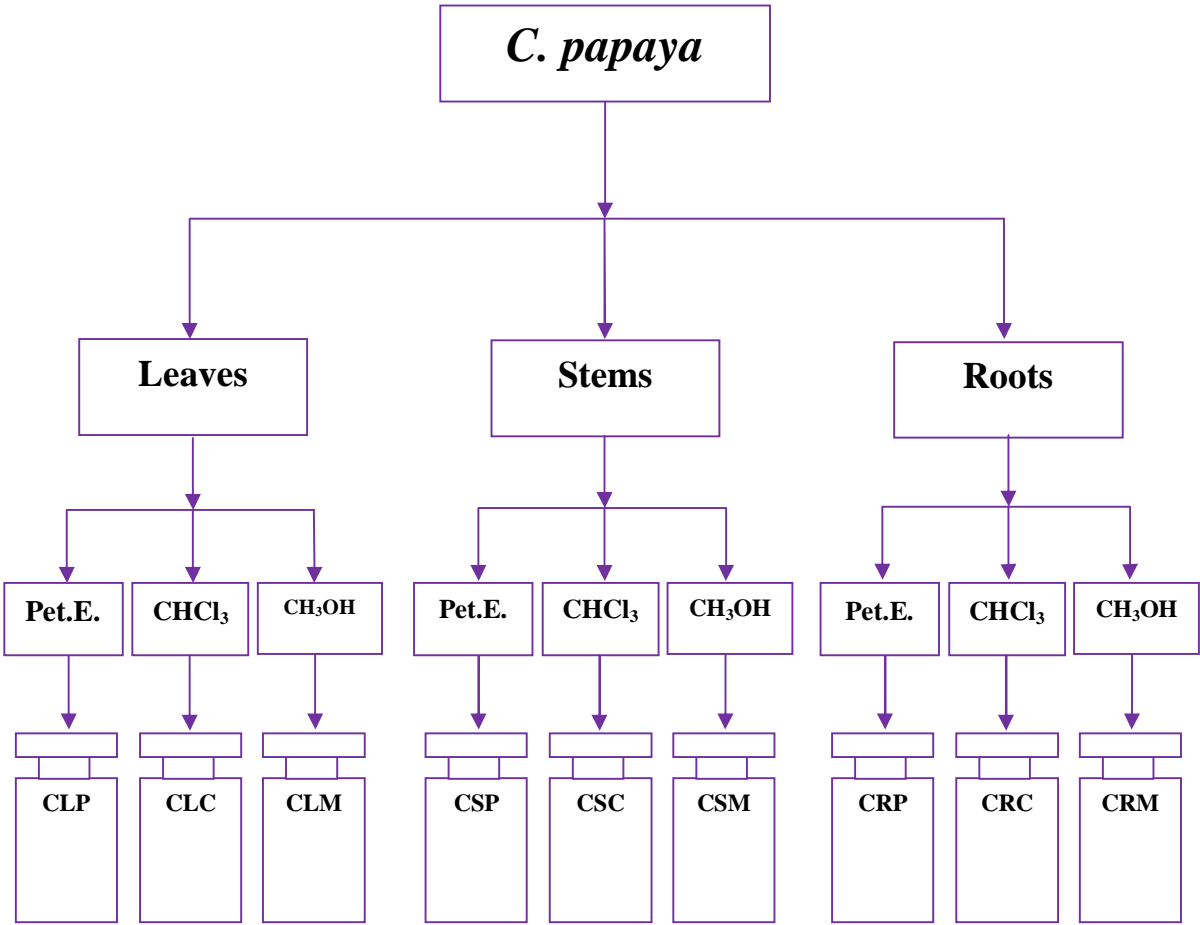

Fig. 2.1: Schematic diagram of extracts collection of *C. papaya* (leaves, stems and roots) by different solvents

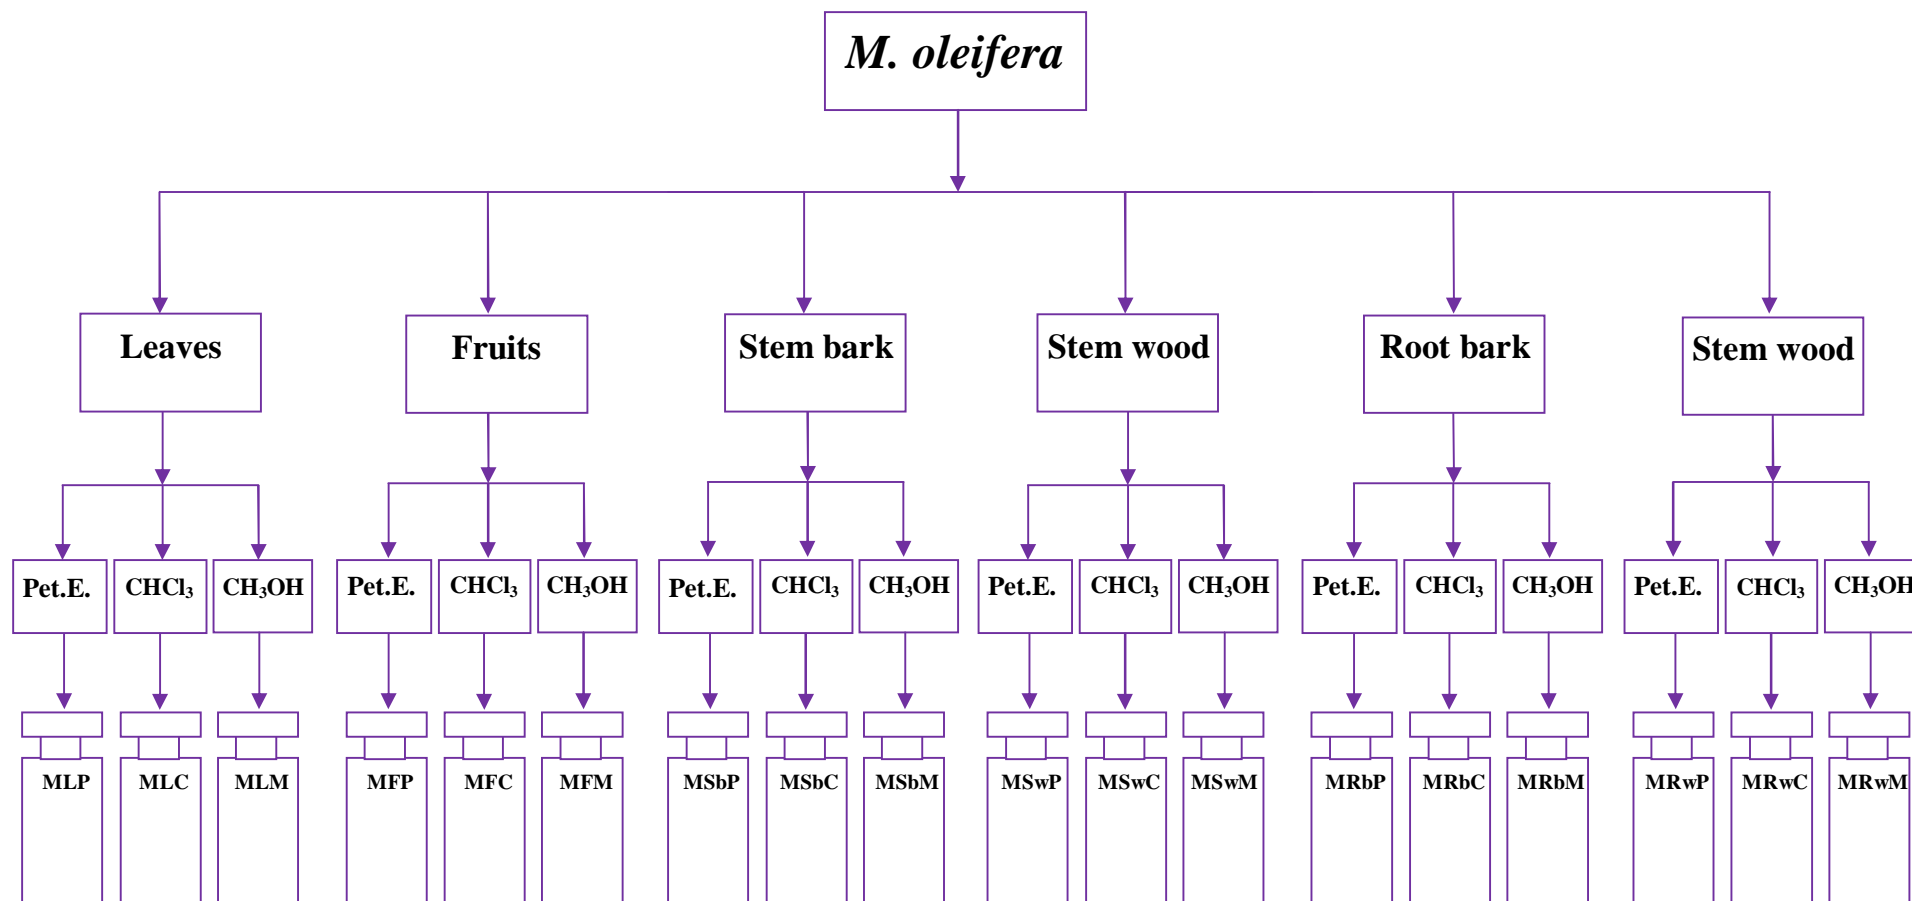

Fig. 2.2: Schematic diagram of extracts collection of *M. oleifera* (leaves, fruits, stem bark, stem wood, root bark and root wood) by different solvents

Fig. 2.3: Schematic diagram of extracts collection of *Mu. sapientum* (leaves, stems and roots) by different solvents

2.1.3. Extraction procedure for the Pet.E., CHCl₃ and CH₃OH solvents

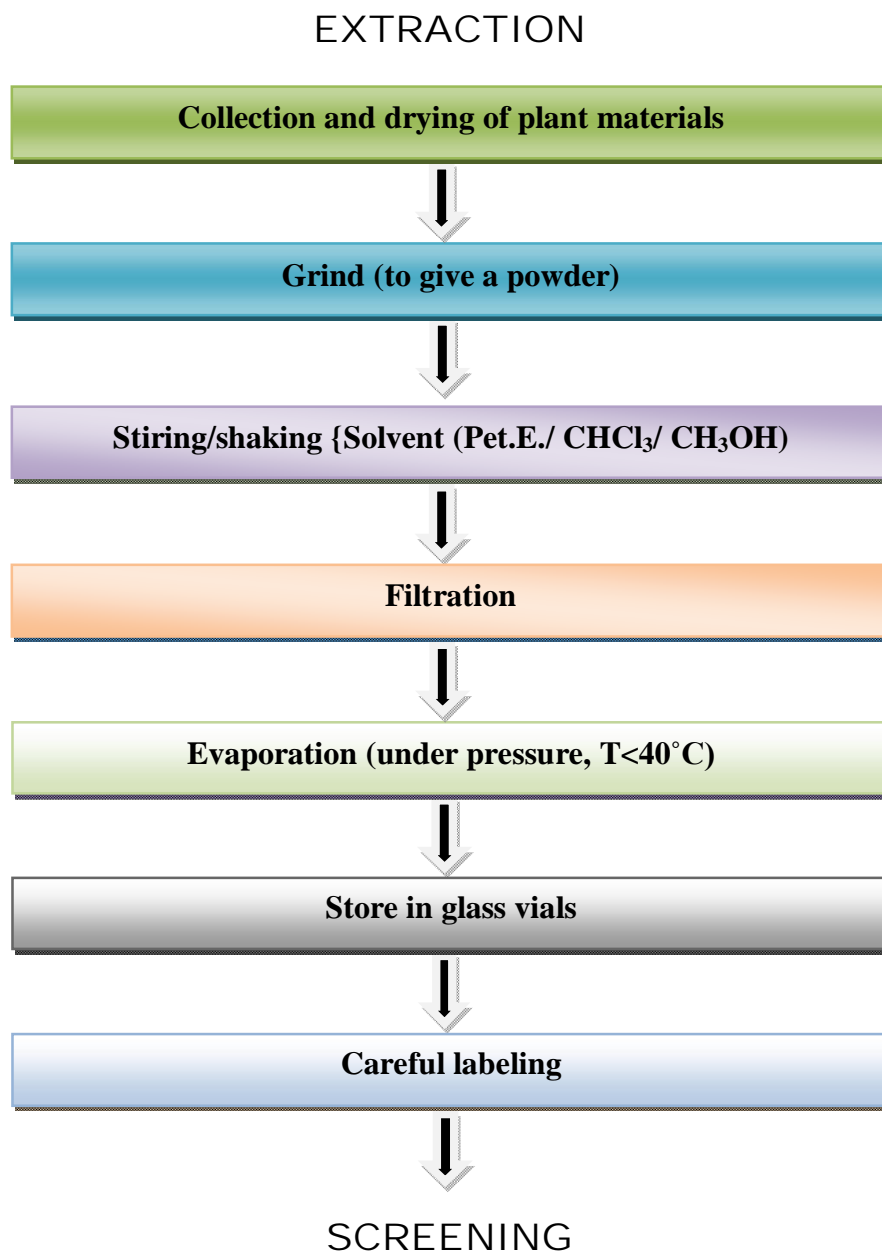

Fig. 2.4: Pathway of extraction

2.2. Bioassays for activity of the collected extracts

Bioassays are typically conducted to measure the effects of a substance on a living organism and are essential in the development of new drugs. It involves a procedure by which the potency or the nature of a substance is estimated by studying its effects on living matter. Bioassays could involve the use of *In Vivo* systems, *ex vivo* systems or *In Vitro* systems.

For the selection of bioassays to employ in research on plant constituents, the first step was to choose suitable target organisms. The complexity of the bioassay has to be designed as a function of the facilities and resources available. A list of bioassays taken in this investigation is shown in Table-2.1.

Table 2.1: A list of test agents used in different bioassays

| Types of tests | Test agents |
|----------------------------------|--|
| 1. Insecticidal | 1. <i>Tribolium castaneum</i> (Hbst.) |
| 2. Cytotoxicity | 2. <i>Artemia salina</i> (L.) |
| 3. Antimicrobial (Antibacterial) | 3. Seven pathogenic bacteria* |
| | 4. Nine isolates from industrial effluent* |

*Names given in Table 2.2

2.2.1. Selection of test organisms

T. castaneum was selected to carry on bioassay for insecticidal potentials of the extractives of *C. papaya*, *M. oleifera* and *Mu. Sapientum*. It was chosen only because it is an easy cultivable and noble laboratory insect. The life histories made this insect as popular choice as test insects for biological studies. For brine shrimp lethality test *A. salina* nauplii was selected, since it is being used in such cases as a model test agent. A number of bacteria were selected to carry out further efficiency tests of the extractives.

2.2.1.1. Collection of test organisms

Adult beetles of *T. castaneum*, used in the present investigation were taken from the stock cultures of the Crop Protection and Toxicology Laboratory, University of

Rajshahi, Rajshahi-6205, Bangladesh and reared as mass- cultures and subcultures to be used in the experimentations. The brine shrimp cysts were collected from any of the aquarium shops of Kataban, Dhaka, Bangladesh.

2.2.1.2. Culture of the test insect *T. castaneum*

Mass cultures were maintained in plastic containers (1200ml) and sub-cultures in beakers (1000ml) with the food medium. The beakers were kept in an incubator at $30^{\circ}\text{C} \pm 0.5^{\circ}\text{C}$ without light and humidity control. Each container and beaker contained 250g and 150g of food respectively. About 200 adults in each container and 100 adults in each beaker were introduced. The cultures were checked in regular intervals and eggs and larvae were separated to increase properly. A crumpled filter paper was placed inside each container and beaker for easy movement of the beetles. The containers and beakers were covered with pieces of muslin cloth tightly fixed with the help of rubber bands to avoid possible escape of the beetles.

2.2.1.3. Preparation of food medium

The whole-wheat flour was used as the food medium for the insect species. The flour was sterilized at 60°C for 24h in an oven. A standard mixture of whole wheat flour with powdered dry yeast in a ratio of 19:1 (Park and Frank, 1948; Park., 1962; Zyromska-Rudzka, 1966; Khalequzzaman *et. al.*, 1994) was used as food medium throughout the experimental period. Both flour and yeast were previously passed through a 250 micrometer sieve and sterilized. The prepared food was not used until at least 15 days after sterilization to allow its moisture content equilibrate with the environment (Khan, 1981).

2.2.1.4. Collection of eggs

About 500 beetles were placed in a 500ml beaker containing food medium. The beaker was covered with a piece of cloth and kept in an incubator at $30 \pm 5^{\circ}\text{C}$. In regular interval the eggs were collected by sieving the food medium by two sieves of 500 and 250 mesh separating the adults and eggs respectively following the methods of Khan and Selman (1981). Eggs were then transferred to Petri dishes (90mm in diameter) and incubated at the same temperature.

2.2.1.5. Collection of newly hatched larvae

After 3-5 days, larvae hatched out in described conditions. Newly hatched larvae were then collected with a fine pointed camel hair brush and then shifted to the fresh food medium for culture. The larvae are yellowish white in color and long cylindrical shape. It appears 1mm in length after hatching and become 6-7mm at maturation.

2.2.1.6. Collection of mature larvae

Most larvae had six instars as reported by Good (1936). According to Good (1936), the larval instars were determined by counting the number of exuviae (larval skin) deposited in the food medium. Two days old larvae was considered as 1st instar larva while 2nd, 3rd, 4th and 5th instars larvae were considered on 4th, 7th, 10th and 13th days from hatching respectively. Depending on these days according to larval instar 16 days old larvae have been considered as mature larvae. Larval cultures were maintained in an incubator in the same procedure at 30°C±5°C without light and humidity control. The food medium was replaced by three days interval to a fresh one to avoid conditioning by the larvae (Park, 1934).

2.2.1.7. Collection of adults

A huge number of beetles were thus reared to get a regular supply of the newly formed adults. When sufficient adults produced in the sub-cultures, they were collected from the food medium. For this purpose some pieces of filter paper were kept inside the beaker on the food. Adults crawled upon the paper and then the paper was taken out with a forceps. Beetles were then collected in a small beaker (100ml) with the help of a fine camel-hair brush.

2.3. Bioassay through surface film method

This is also one basic application method for doses of toxic substances to any insect population. The test material has been dissolved in an organic solvent with a certain concentration to apply to a Petri dish of known surface area. After application being volatile the solvent evaporates out immediately simply with the atmospheric temperature. Thus the ingredient goes to make a film on the surface of the Petri dish. Released insects within this captivity might have contact with the substance distributed evenly on the floor. However, being covered with the upper lid of the Petri dish there

could have a captive environment with the extract distributed even in the air inside and may cause mortality by suffocation. Mortality due to suffocation may cause promptly if there is any volatile bioactive principles in the test material. All extracts were diluted with the solvents in which they were extracted and the actual amount of extracted matter in a dose was recorded. The application of dose was carried out by residual film method (Busvine, 1971).

2.3.1. Preparation of doses with the crude extracts for the surface film test

In this investigation dose-mortality efficiency was evaluated through surface film experiment with series of doses applied on *T. castaneum* adults. All the three viz. Pet.E., CHCl_3 and CH_3OH extracts of the study plants were applied against *T. castaneum* adults. For each samples, an 'Ad Hoc' test was done before final experimentation. 50mg extract sample was weighed and taken in a small glass vial, and then 1ml of the same chemical (1ml Pet.E. for the Pet.E. extracts) was added to dissolve initially for preparing 2.547mg cm^{-2} dose. This process was also maintained during final experiment. Separate vials were taken for each of the doses and the doses were maintained in three replications.

2.3.2. Application of doses in the surface film test

To conduct surface film activity test 50mm Petri dishes were taken for all doses and their replicates, 1ml of each of the doses were poured into the lower part of the Petri dishes and allowed them to dry out. Being volatile the solvent was evaporated out within a few minutes. Ten insects were released in each of the treated Petri dish. A control experiment by applying the only solvent to the lower part of the Petri dish was also set at the same time under the same condition (Plate 2.5).

Doses selected for different extracts for the final experiment were as follows:

- *C. papaya* leaf Pet.E.: 1.274, 1.019, 0.764, 0.510 and 0.255mg cm^{-2}
 - stem Pet.E.: 2.038, 1.783, 1.529, 1.274, 1.019 and 0.764mg cm^{-2}
 - root Pet.E.: 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm^{-2}
 - stem CHCl_3 : 4.076, 3.057, 2.038, 1.529 and 1.019mg cm^{-2}
 - leaf CH_3OH : 2.038, 1.529, 1.019, 0.764, 0.510, 0.255 and 0.127mg cm^{-2}
 - stem CH_3OH : 1.274, 1.019, 0.764, 0.510, 0.255 and 0.127mg cm^{-2}

- root CH₃OH: 1.019, 0.764, 0.510, 0.255 and 0.127mg cm⁻²
- *M. oleifera* stem bark Pet.E.: 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm⁻²
 root bark Pet.E.: 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm⁻²
 root wood Pet.E.: 1.783, 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm⁻²
 fruit CH₃OH: 2.038, 1.529, 1.019, 0.764 and 0.510mg cm⁻²
 stem bark CH₃OH: 1.274, 1.019, 0.764, 0.510, 0.255 and 0.127mg cm⁻²
 stem wood CH₃OH: 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm⁻²
 root bark CH₃OH: 1.274, 1.019, 0.764, 0.510, 0.255 and 0.127mg cm⁻²
 root wood CH₃OH: 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm⁻²
- *Mu. sapientum* leaf Pet.E.: 2.038, 1.783, 1.529, 1.274, 1.019 and 0.764mg cm⁻²
 stem Pet.E.: 2.038, 1.529, 1.019, 0.510 and 0.255mg cm⁻²
 root Pet.E.: 1.783, 1.529, 1.274, 1.019, 0.764, 0.510 and 0.255mg cm⁻²
 leaf CH₃OH: 1.529, 1.274, 1.019, 0.764, 0.510, 0.255 and 0.127mg cm⁻²
 stem CH₃OH: 0.510, 0.382, 0.255, 0.127 and 0.064mg cm⁻²
 root CH₃OH: 0.764, 0.637, 0.510, 0.382, 0.255 and 0.127mg cm⁻²

2.3.3. Observation of mortality in the surface film tests

After completing the all the arrangements treated Petri dishes were placed in a secured place at room temperature. The whole experiment was observed from time to time and mortality was observed by after ½, 6, 12, 24, 36 and 48h the data was recorded. A simple microscope was used to check each and every beetle by tracing natural movement of its organs. In some cases hot needle was taken closer to the bodies (without movement) to confirm death. Attention was also paid to recovery of the insects if occurred.

2.3.4. Statistical analysis

The mortality records of the residual film experiments done *T. castaneum* adults on adults were corrected by the Abbott's (1925) formula:

$$P_r = \frac{P_o - P_c}{100 - P_c} \times 100$$

Where,

P_r = Corrected mortality (%)

P_o = Observed mortality (%)

P_c = Control mortality (%), sometimes called natural mortality (%).

Then mortality percentages were subjected to statistical analysis according to Finney (1947) and Busvine (1971) by using 'computer software'. The dose-mortality relationship was expressed as a median lethal dose (LD_{50}).

Plate 2.5: Bioassay with plant extracts on *T. castaneum* adults by surface film method

2.4. Bioassay through brine shrimp lethality test

2.4.1. Culture of *A. salina*

In the laboratory condition *A. salina* are very nice to grow, since the rate of successful hatches is very high. To conduct cytotoxicity test the brine shrimp nauplii were used because of its easy hatching and use in the experiment. The eggs (cysts) were collected from aquarium shops. For their easy hatching and use the requirements were as follows:

- Salt water: 38g salt per liter of water;
- Temperature: 26-28°C (80-82°F);
- Light: The beaker was placed near a window with sunlight before hatching;

- Aeration: Picking up some water carefully with a spoon and let it drop back into the beaker once a day [but a small aquarium pump with a little air-stone is better];
- Helpful Hint: Brine shrimp egg is sometimes very buoyant. Swirl the water to knock down eggs;

The cysts absorb water and if the sun is shining (a signal for growing algae and other plankton) they hatch after 24 to 48h, depending on their environment. Freshly hatched *A. salina* called nauplii and have a size of just 0.25mm. They molt like any other crawfish when they grow to adult they molt about 17 times. Freshly hatched nauplii were used in this experiment.

2.4.2. Experimental design for the lethality test

Brine shrimp cysts were hatched in simulated seawater to get nauplii. Test samples are prepared by the addition of calculated amount of DMSO (dimethyl sulfoxide) for obtaining desired concentration of test sample. The nauplii were counted by visual inspection and were taken in Test-tubes containing 5ml of simulated seawater. Then samples of different concentrations were added to the pre marked test-tubes through pipettes. The test-tubes were left for 24h and then the nauplii were counted again to find out the cytotoxicity of the test agents and compared to the results with the control.

Test materials:

- Brine Shrimp (*A. salina*) cysts
- Iodine-free salt
- Small tank/ beaker to hatch the shrimp
- Pasteur pipette (1ml and 5ml)
- Test tubes (20ml)
- Magnifying glass

2.4.3. Preparation of simulated seawater (brine water)

Since the lethality test involves the culture of brine shrimp nauplii that is, the nauplii should be grown in the seawater. Seawater contains 3.8% of NaCl. Accordingly 3.8% sodium chloride solution was made by dissolving sodium chloride (38g) in normal pond water (1000ml) and was filtered off.

Plate 2.6: Bioassay with plant extracts on *A. salina* nauplii by brine shrimp lethality test

2.4.4. Hatching of the brine shrimp nauplii

Brine water was taken in a small tank and *A. salina* cysts (1.5g L^{-1}) were added. Constant temperature (37°C) and sufficient light were maintained to give the sufficient aeration. After 24 hours, matured shrimp as nauplii was collected and used for the experiment.

2.4.5. Experimentation of lethality test

The Pet.E., CHCl_3 , and CH_3OH extracts of different parts of *C. papaya*, *M. oleifera* and *Mu. sapientum* samples were applied against brine shrimp nauplii. For each samples, an 'Ad Hoc' test was done before final experimentation. Two milligram extract sample was weighed and taken in a small glass vial, then 1-2 drops of pure Dimethyl sulfoxide (DMSO) added to dissolve the extract initially and 1ml of pond water was taken into the vial to mix up the sample extract with water to prepare a 200ppm concentration. When it mixed up completely it was added to the test-tube (10ml marked) for conducting tests. This process was also maintained during final experiment. Separate vials were taken for each of the doses. The replicates were maintained for each of the concentrations.

Concentrations selected for the different extracts for the final experiment:

- *C. papaya* leaf Pet.E.: 250, 200, 150 and 100ppm
 - stem Pet.E.: 75, 50, 25, 12.5 and 6.25ppm
 - root Pet.E.: 100, 80, 60, 40 and 20ppm
 - leaf CHCl_3 : 200, 150, 100, 75, 50 and 25ppm
 - stem CHCl_3 : 75, 50, 25, 12.5 and 6.25ppm
 - root CHCl_3 : 100, 75, 50, 25, 12.5 and 6.25ppm
 - leaf CH_3OH : 100, 80, 60, 40 and 20ppm
 - stem CH_3OH : 200, 150, 100, 50 and 25ppm
 - root CH_3OH : 200, 150, 100, 50 and 25ppm
- *M. oleifera* fruit Pet.E.: 80, 70, 60, 50, 40 and 30ppm
 - leaf Pet.E.: 200, 150, 100, 75, 50 and 25ppm
 - stem wood Pet.E.: 80, 70, 60, 50, 40 and 30ppm
 - root bark Pet.E.: 100, 90, 80, 70, 60 and 50ppm
 - root wood Pet.E.: 100, 90, 80, 70, 60 and 50ppm

fruit CHCl_3 : 200, 150, 100, 75, 50 and 25ppm
stem bark CHCl_3 : 100, 75, 50, 25, 12.5 and 6.25ppm
stem wood CHCl_3 : 75, 50, 25, 12.5 and 6.25ppm
root bark CHCl_3 : 50, 25, 12.5, 6.25, 3.13 and 1.56ppm
root wood CHCl_3 : 200, 150, 100, 50, 25, 12.5 and 6.25ppm
fruit CH_3OH : 200, 150, 100, 50 and 25ppm
leaf CH_3OH : 200, 150, 100, 50 and 25ppm
stem bark CH_3OH : 90, 70, 50, 30 and 10ppm
stem wood CH_3OH : 250, 200, 150, 100, 50, 25 and 12.5ppm
root bark CH_3OH : 100, 50, 25, 12.5, 6.25 and 3.13ppm
root wood CH_3OH : 300, 250, 200, 150, 100 and 50ppm

- *Mu. sapientum* leaf Pet.E.: 200, 150, 100, 75, 50 and 25ppm
stem Pet.E.: 90, 70, 50, 30 and 10ppm
root Pet.E.: 100, 80, 60, 40 and 20ppm
leaf CHCl_3 : 100, 75, 50, 12.5 and 6.25ppm
stem CHCl_3 : 50, 40, 30, 20 and 10ppm
root CHCl_3 : 80, 70, 60, 50 and 40ppm
leaf CH_3OH : 200, 150, 100, 50 and 25ppm
stem CH_3OH : 150, 100, 75, 50 and 25ppm
root CH_3OH : 200, 150, 100, 50 and 25ppm

2.4.6. Application of doses to the nauplii

In each of the five test tubes, 5ml brine water (3.8%) containing 10 brine shrimp nauplii with the help of a pasture pipette. Specific volume of each samples were transferred from the stock solution to the respective test tubes to get the target volume. The volume of DMSO should not exceed $10\mu\text{l ml}^{-1}$ of the brine solution, because above this concentration toxicity due to DMSO may arise.

2.4.7. Observation of lethality

The test tubes containing the nauplii along with the treated brine water were kept on a rack near the window in the laboratory. After 6, 12, 18 and 24h, the test tubes were

observed. The number of survived nauplii in each test tube was counted and the results were noted. From this, percentages of mortality of brine shrimp nauplii were calculated.

2.4.8. Analysis of data

Data were analyzed statistically by Probit analysis as done previously in surface film test and here the dose-mortality relationship was expressed as the median lethal concentration (LC_{50}).

2.5. Selection of microorganisms for antibacterial test agents

Antimicrobial activity can be detected by observing the growth response of various microorganisms to the different plant extracts or isolated compounds from them, which are placed in contact with them. Seven pathogenic bacteria were selected for the antibacterial activity test, two of which were gram positive and the remaining were gram negative. The bacterial strains used for this investigation are listed in the following Table 2.2.

| Sl. No. Gram negative | Sl. No. Gram positive |
|---|--|
| 1 <i>Escherichia coli</i> | 1 <i>Bacillus subtilis</i> |
| 2 <i>Klebsiella pneumoniae</i> | 2 <i>Staphylococcus aureus</i> |
| 3 <i>Salmonella enteritidis</i> | |
| 4 <i>Shigella flexneri</i> | |
| 5 <i>Shigella sonnei</i> | |
| Nine isolates from the industrial effluents | |
| 1 <i>Escherichia coli</i> I (Isolate 4) | 1 <i>Bacillus cereus</i> (Isolate 1) |
| 2 <i>Escherichia coli</i> II (Isolate 5) | 2 <i>Bacillus subtilis</i> (Isolate 8) |
| 3 <i>Klebsiella oxytoca</i> (Isolate 2) | 3 <i>Staphylococcus aureus</i> (Isolate 3) |
| 4 <i>Cytrobacter freundii</i> (Isolate 6) | |
| 5 <i>Proteus vulgaris</i> (Isolate 7) | |
| 6 <i>Salmonella typhimurium</i> (Isolate 9) | |

2.5.1. Collection and culture of test bacteria

The pure cultures were collected from the microbiological research laboratory of the Department of Biochemistry, Rajshahi University.

2.5.1.1. Culture media

A number of culture media are available to demonstrate the antibacterial activity. These are as follows:

- i) Nutrient agar medium
- ii) Nutrient broth medium
- iii) Mueller-Hinton medium
- iv) Tryptic Soy broth (TSB) medium
- v) Trypticase Soy agar medium
- vi) Staphylococcus defined medium
- vii) Adams and Roe medium
- viii) NTH agar or broth medium.

While the nutrient agar medium was adopted to conduct experiments in this investigation.

Table 2.3: The list of the composition of nutrient agar medium.

| Ingredient | Amount |
|--------------------|-----------------|
| Bactopeptone | 0.5g |
| Sodium chloride | 0.5g |
| Bactoyeast extract | 1.0g |
| Bactoagar | 2.0g |
| Distilled water | 100ml |
| pH | 7.2±0.1 at 25°C |

2.5.1.2. Preparation of fresh culture of the pathogenic organisms

The nutrient broth medium was prepared and dispersed in a number of clean test tubes to prepare broth (5ml in each test tube). The test tubes were plugged with cotton and sterilized in an autoclave at 121°C and 15lbs sq⁻¹ inch pressure for 15min. After sterilization, the test tubes were kept in an inclined position for cool. The test organisms

were transferred to the nutrient broth from the pure cultures with the help of an inoculating loop in an aseptic condition. Burning the loop after each transfer of microorganism was done to avoid contamination very carefully. The inoculated broth was then incubated at 37.5°C for 24h to assure the growth of test organisms. These fresh cultures were used for the sensitivity tests.

2.5.2. Selection of test method

(i) Primary assay

It is essentially a qualitative or semi-qualitative test that indicates the sensitivity or resistance of microorganisms to the compound. However, this technique cannot be used to distinguish between bacteriostatic and bactericidal agents (Reiner, 1980).

The primary assay can be done in three ways such as-

- A. Diffusion method
- B. Dilution method and
- C. Bio-autographic method.

Among these methods the disc diffusion method (Bauer *et al.*, 1966; Reiner, 1982) is widely acceptable for the preliminary evaluation of antimicrobial activity. It uses different concentrations of the agents absorbed on sterile filter paper discs. There is no standardized method for expressing the results of antimicrobial screening (Ayafar *et al.*, 1982). Some investigators use the diameter of the zone of inhibition or the minimum weight of extract that inhibits the growth of a microorganism. Disc diffusion is essentially a qualitative or semi-quantitative test indicating the sensitivity or resistance of microorganisms to the test material. No distinction between bacteriostatic and bactericidal activity can be made by this method (Reiner, 1982). However, the diffusion method was used in this investigation.

Principles of the diffusion method

Diffusion assay (Barry, 1976) is based on the ability of antibiotics to diffuse from a confined source through the nutrient agar gel and create a concentration gradient. If the agar is seeded or streaked with a sensitive organism, a zone of inhibition will result where the concentration exceeds the minimum inhibitory concentration (MIC) for the particular organism.

In this method, measured amount of the test samples are dissolved in definite volumes of solvent to give solutions of known concentrations ($\mu\text{g ml}^{-1}$). The sterile (BBL, Cocksville, USA) filter paper (5mm diameter) disc were impregnated with known amounts of the test substances and dried. These test material discs were placed on plates containing nutrient agar medium seeded with the test organisms. These plates were kept at low temperature (4°C) for 24h to allow maximum diffusion.

A number of events took place simultaneously which includes:

- i) The dried discs absorb water from the agar medium and the material under test was dissolved.
- ii) The test material diffuses from the discs to the surrounding medium according to the physical law that controls the diffusion of molecules through agar gel.
- iii) There was a gradual change of test material concentration in the agar surrounding each disc.

To determine the most optimal concentration of extracts to be used in this study, sterile 7.5mm filter paper disks were treated with 200 and 400 μl Pet.E, CHCl_3 and CH_3OH extracts (while the only solvent used as control). The bacteria were inoculated on full-strength Nutrient Agar (Qualigens Fine Chemicals, Prod # 58673) by suspending loops in sterile de-ionized water. The bacterial suspension was then smeared on agar plates with a sterile glass-rod to ensure the entire surface of the agar had an even coating of the bacterial suspension. The plates were divided into several areas and one filter paper disk was placed on each of the areas. The plates are then kept in an incubator (37°C) for 12 to 18h to allow the growth of the organisms. If any of the test material has antimicrobial activity, it will inhibit the growth of microorganisms just giving a clear distinct zone called 'Zone of Inhibition'. Biological activity of the *C. papaya*, *M. oleifera* and *Mu. sapientum* components on bacterial growth were quantified by measuring the diameter of the zones of inhibition in term of mm. The size of the inhibitory zones depends principally on the following factors:

- i) Intrinsic antimicrobial sensitivity of the test sample,
- ii) Growth rate of the test microorganisms,
- iii) Diffusion rate of the freshly seeded test organisms,

- iv) Concentration of the freshly seeded test organisms,
- v) Amount of test sample on disc,
- vi) Thickness of the test medium in the Petri dishes,
- vii) Composition of the culture medium,
- viii) Size of inocula,
- ix) Time of incubation,
- x) Temperature of incubation.

(ii) Secondary assay

The simple assay quantifies the relative potency, such as minimum inhibitory concentration (MIC) of the lowest concentration of an antimicrobial agent required to inhibit the growth of the microorganisms *In Vitro*. It is done by serial dilution technique (Reiner, 1980).

Test materials used for the study

- Pet.E., CHCl₃ and CH₃OH extracts of different parts of *C. papaya*, *M. oleifera* and *Mu. Sapientum*.
- Ampicillin (10µg disc⁻¹) as standard discs.

Apparatus and reagents to conduct antibacterial assay

- i) Blank sterilized filter paper discs (diam. 5mm)
- ii) Petri dishes (diam. 120mm)
- iii) Test tubes
- iv) Inoculating loop
- v) Spirit burner and a match box
- vi) Sterile forceps
- vii) Sterile cotton
- viii) Laminar air flow unit (Biocraft & Scientific Industries, INDIA)
- ix) Micropipette (10 -100µl)
- x) Autoclave (ALP Co. Ltd. KT- 30L, JAPAN)
- xi) Incubator (Lab Tech, Model: LIB -030M, Korea)
- xii) Refrigerator
- xiii) Punch machine
- xiv) Beaker
- xv) Nutrient agar media (DIFCO)

- xvi) Solvent (Pet.E., CHCl_3 and CH_3OH)
- xvii) Vials
- xviii) Rectified spirit
- xix) Alcohol (95%)

2.5.3. Sterilization procedures

The antibacterial screening was carried out in a laminar airflow unit and all types of precautions were highly maintained to avoid any type of contamination during the test. UV light was switched on for half an hour before working in the laminar hood to avoid any accidental contamination. Petri dishes and other glass-wares were sterilized in the autoclave at 121°C temperature and a pressure of 15lbs/sq inch for 15min. Micropipette tips, culture media, cotton, forceps, blank discs, etc were also sterilized.

2.5.4. Preparation of the test plates

The test plates were prepared according to the following procedure:

- (i) The nutrient agar medium prepared in the previous section was poured in 15ml quantity in each in the clean test tubes and plugged with cotton.
- (ii) The test tubes and a number of Petri dishes were sterilized in an autoclave at 121°C and 15lbs/sq inch pressure for 15min and were transferred into laminar airflow unit and then allowed to cool to about 45°C to 50°C .
- (iii) The test organism was transferred from the fresh subculture to the test tube containing 15ml autoclaved medium with the help of an inoculating loop in an aseptic condition. Then the test tube was shaken by rotation to get a uniform suspension of the organism.
- (iv) The bacterial suspensions were immediately transferred to the sterile Petri dishes in an aseptic area. The Petri dishes were rotated several times, first clockwise and then anticlockwise to assure homogenous distribution of the test organisms. The media were poured into Petri dishes in such a way as to give a uniform depth of approximately 4mm.
- (v) Finally, after medium was cooled to room temperature in laminar airflow unit, it was stored in a refrigerator (4°C).

2.5.5. Preparation of discs containing samples

For the preparation of discs containing samples, following procedure was utilized:

(a) Sample discs

Sterilized filter paper discs (5mm diam.) were taken by the forceps in to the plates. Sample solutions of desired concentrations were applied on the discs with the help of a micropipette in an aseptic condition. These discs were left for a few minutes in aseptic condition for complete removal of the solvent.

(b) Standard discs

These were used to compare the antibacterial activity of the test material. In the present study, Ciprofloxacin discs containing $10\mu\text{g disc}^{-1}$ of antibiotic Ciprofloxacin were used as standard discs for comparison purpose.

2.5.6. Placement of the discs and incubation

For the placement of the discs, the following procedure was utilized:

- (i) By means of a pair of sterile forceps, the sample impregnated discs were placed gently on the solidified agar plates seeded with the test organisms to ensure contact with the medium.
- (ii) The plates were then kept in a refrigerator at 4°C for 24h in order to provide sufficient time to diffuse the antibiotics into the medium.
- (iii) Finally, the plates were incubated at 37.5°C for 24h in an incubator.

2.5.7. Precaution

The discs were placed in such a way that they were not closer than 15mm to the edge of the plate and far enough apart to prevent over lapping the zones of inhibition.

2.5.8. Measurement of the zones of inhibition

After incubation, the antibacterial activities of the test samples were determined by measuring the diameter of inhibitory zones in term of mm with a transparent scale.

2.6. Isolation and Identification of bacteria from industrial effluent

2.6.1. Collection of effluent

The tannery effluent samples were collected from Rayerbazar sluice gate area under Dhaka City Corporation (South) adjacent to Hazaribagh tannery during March, 2014. The samples were collected in bags for bacteriological analysis and sterile plastic container for waste water analysis and transported to the laboratory. We collected three samples viz. sample 1: behind the sluice gate point of 500m far (waste water), sample 2: sludge of adjacent sluice gate point and sample 3: sludge with water of adjacent sluice gate point.

2.6.2. Physico-chemical analysis of effluent

Physico-chemical analysis of water is the analysis of the physical and chemical properties of a sample of water, often to determine if the water is suitable for drinking or supporting aquatic life.

The remaining physico-chemical parameters (*pH*; Electrical Conductivity, EC; Total Dissolved Solids, TDS; Biological Oxygen Demand, BOD; Chemical Oxygen Demand, COD; heavy metal ions) were determined as soon as the sample was brought to the laboratory. Analysis of different metal ions in the effluent sample was determined by Atomic Absorption Spectrophotometer (AAS) as per the standard methods (APHA, 2005).

2.6.2.1. *pH*

Measuring the *pH* for water analysis is an important physical parameter. The *pH* scale ranges from 0 to 14, with pure water at seven for neutral. If the water is under seven, that means there is acidic compound present. If it is above seven, there are alkalis present.

2.6.2.2. Electrical Conductivity (EC)

Electrical conductivity is used to measure water's ability to conduct an electrical current. Nutrients, minerals, metals and pollutants can affect this ability.

2.6.2.3. Total Dissolved Solids (TDS)

Total dissolved solids (TDS) comprise inorganic salts and small amounts of organic matter that are dissolved in water. Many dissolved substances are undesirable in water. Dissolved minerals, gases and organic constituents may produce aesthetically displeasing colour, taste and odor. Some dissolved organic chemicals may deplete the dissolved oxygen in the receiving waters and some may be inert to biological oxidation, yet others have been identified as carcinogens.

2.6.2.4. Biological Oxygen Demand (BOD)

The biological oxygen demand determination is a chemical procedure for determining the amount of dissolved oxygen needed by aerobic organisms in a water body to break the organic materials present in the given water sample at certain temperature over specific period of time.

2.6.2.5. Chemical Oxygen Demand (COD)

The chemical oxygen demand (COD) test is commonly used to indirectly measure the amount of organic compounds in water. Most applications of COD determine the amount of organic pollutants found in surface water (e.g. lakes and rivers) or wastewater, making COD a useful measure of water quality. It is expressed in milligrams per liter (mg L^{-1}) also referred to as ppm (parts per million), which indicates the mass of oxygen consumed per liter of solution.

2.6.2.6. Fluoride

Fluoride is considered to be one of the major ions of seawater. Fluoride is used in certain industrial processes and consequently occurs in the resulting wastewaters.

2.6.2.7. Chloride

Chloride anions are usually present in natural waters. A high concentration occurs in waters that have been in contact with chloride-containing geological formations. Otherwise, a high chloride content may indicate pollution by sewage or industrial wastes or by the intrusion of seawater or saline water into a freshwater body or aquifer.

2.6.2.8. Nitrite

Nitrite is an unstable, intermediate stage in the nitrogen cycle and is formed in water either by the oxidation of ammonia or by the reduction of nitrate. Thus, biochemical

processes can cause a rapid change in the nitrite concentration in a water sample. In natural waters nitrite is normally present only in low concentrations (a few tenths of a milligram per litre). Higher concentrations may be present in sewage and industrial wastes, in treated sewage effluents and in polluted waters.

2.6.2.9. Nitrate

Nitrates generally occur in trace quantities in surface waters but may attain high levels in some ground waters. Nitrite in water is either due to oxidation of ammonium compounds or due to reduction of nitrate. It can be toxic to certain aquatic organisms even at concentration of 1 mg L^{-1} . In excessive limits, it contributes to the illness known as methenoglobinemia in infants.

2.6.2.10. Bromide

Inorganic bromide is widely distributed in nature. Its natural physiological role in animal life is unknown. It was once used in sedatives and headache remedies like Bromo-Seltzer until it was withdrawn because of concerns about toxicity. When it shows up at elevated levels in freshwater, it is due to human activities.

2.6.2.11. Phosphate

Phosphate occurs in traces in many natural waters, and often in appreciable amounts during periods of low biologic productivity. Traces of phosphate increase the tendency of trouble some algae to grow in reservoirs. Waters receiving raw or treated sewage, agricultural drainage, and certain industrial waters normally contain significant concentrations of phosphate. Also phosphate is frequently added to domestic and industrial waters in various forms. Phosphate analyses are made primarily to control chemical dosage, or as a means of tracing flow of contamination.

2.6.2.12. Sulphate

Sulphate is an abundant ion in the earth's crust and its concentration in water can range from a few milligrams to several thousand milligrams per litre. Industrial wastes and mine drainage may contain high concentrations of sulphate. Sulphate also results from the breakdown of sulphur-containing organic compounds. Sulphate is one of the least toxic anions.

2.6.2.13. Concentration of metal ions in effluent

The presence of various heavy metals in industrial wastewaters is of serious concern because they are highly toxic, non-biodegradable, carcinogenic, and continuous deposition into receiving lakes, streams and other water sources within the vicinity causes bioaccumulation in the living organisms.

Arsenic (As): Arsenic is an element used for several human activities. It is a very poisonous element; prolonged exposure to it or ingestion of small amounts can cause long term effects, such as cancer. In nature, as is present in the form of various minerals, such as arsenpyrite (FeAsS) and lollyngite (FeAs_2). Leaks of these minerals into ground water can cause contamination.

Chromium (Cr): Chromium is the most abundant element in Earth's crust. Chromium compounds are found in the environment, due to erosion of chromium-containing rocks and can be distributed by volcanic eruptions. In larger amounts and in different forms, chromium can be toxic and carcinogenic. The most prominent example of toxic chromium is hexavalent chromium (Cr(VI)). Abandoned chromium production sites often require environmental cleanup.

Cadmium (Cd): Cadmium can mainly be found in the earth's crust. It always occurs in combination with zinc. Cadmium is an extremely toxic metal commonly found in industrial workplaces. Due to its low permissible exposure limit, overexposures may occur even in situations where trace quantities of cadmium are found. Cadmium is used extensively in electroplating, although the nature of the operation does not generally lead to overexposures. Cadmium is also found in some industrial paints and may represent a hazard when sprayed. Operations involving removal of cadmium paints by scraping or blasting may pose a significant hazard.

Cobalt (Co): In nature, cobalt is frequently associated with nickel and both are characteristic components of meteoric iron. Free cobalt is not found in on Earth due to the amount of oxygen in the atmosphere and chlorine in the ocean. Oxygen and chlorine are abundant enough in the upper layers of the Earth's crust so as to make native metal cobalt formation extremely rare. It is one of the first transition metals. Small amounts of cobalt compounds are found in most rocks, soil, plants, and animals. Cobalt is the active center of coenzymes called cobalamins, the most common example

of which is vitamin B₁₂. As such it is an essential trace dietary mineral for all animals. Cobalt in inorganic form is also an active nutrient for bacteria, algae and fungi.

Copper (Cu): Copper is essential to all living organisms as a trace dietary mineral. Copper compounds are used as bacteriostatic substances, fungicides, and wood preservatives. Hazards and risks associated with copper: copper metal powder is a fire hazard. Unless known otherwise, all copper compounds should be regarded as toxic. Pollution from industrial smoke is a problem.

Iron (Fe): Iron is an abundant element in the earth's crust, but exists generally in minor concentrations in natural water systems. The form and solubility of iron in natural waters are strongly dependent upon the pH and the oxidation- reduction potential of the water. Iron is found in the +2 and +3 oxidation states. In a reducing environment, ferrous (+2) iron is relatively soluble. An increase in the oxidation-reduction potential of the water readily converts ferrous ions to ferric (+3) and allows ferric iron to hydrolyse and precipitate as hydrated ferric oxide. The precipitate is highly insoluble.

Lead (Pb): Lead is also a hazardous element employed in many processes. Exposure or ingestion of lead can cause serious harm to the nervous system; young children seem particularly affected, as they may experience long-term effects, such as learning disabilities. In nature, lead is found in ores, such as galena (PbS), anglesite (PbSO₄) and cerussite (PbCO₃). Today, its main industrial application is in the production of batteries, especially for cars. Lead is also used in construction, due to its resistance to corrosion; some lead-based compounds are employed in the manufacturing of paints, and in many electronic devices.

Manganese (Mn): Manganese also functions in the oxygen-evolving complex of photosynthetic plants. The element is a required trace mineral for all known living organisms. In larger amounts, and apparently with far greater activity by inhalation, it can cause a poisoning syndrome in mammals, with neurological damage which is sometimes irreversible. Manganese compounds are less toxic than those of other widespread metals.

Nickel (Ni): Nickel is one of four elements that are ferromagnetic around room temperature. The metal is chiefly valuable in the modern world for the alloys it forms;

about 60% of world production is used in nickel-steels (particularly stainless steel). As a compound, nickel has a number of niche chemical manufacturing uses, such as a catalyst for hydrogenation. Enzymes of some microorganisms and plants contain nickel as an active site, which makes the metal an essential nutrient for them. Nickel can have an impact on human health through infectious diseases arising from nickel-dependent bacteria.

Potassium (K): Potassium is a relatively abundant element. Most industrial chemical application of potassium employ the relatively high solubility in water of potassium compounds. Potassium metal has only a few special applications, being replaced in most chemical reactions with sodium metal. Potassium is an extremely active metal, which reacts violently with oxygen and water in air. Potassium ions are necessary for the function of all living cells. Potassium ion diffusion is a key mechanism in nerve transmission, and potassium depletion in animals, including humans, results in various cardiac dysfunctions.

Zinc (Zn): Zinc is an essential and beneficial element in body growth. Concentrations above 5 mg/l may cause a bitter astringement taste and opalescence in alkaline water. Zinc most commonly enters the domestic supply from deterioration of galvanized iron and dezincification of brass. Zinc in water may also come from individual water pollution.

2.6.3. Isolation of bacteria from industrial effluent

2.6.3.1. Equipments and media for the isolation of bacteria

- i) Petri dishes (90mm diam.)
- ii) Test tubes
- iii) Beaker
- iv) Inoculating loop
- v) Sterile cotton
- vi) Sterile forceps
- vii) Spirit burner and a match box
- viii) Eppendorf tube
- ix) Micropipette (10µl-100µl) and sterile tips
- x) ESCO, Class II Biological Safety Cabinet (Model: AC2- 4E1,Indonesia)

- xi) Autoclave (HIRAYAMA)
- xii) Incubator (JEIO TECH, Model: IB- 01E, Korea)
- xiii) Refrigerator (SHARP, Ag⁺ Nano Deodorizer)
- xiv) Microwave oven
- xv) Mikrobiologie (Nutrient agar) Merck, Germany
- xvi) Different kinds of media and reagents
- xvii) Rectified spirit
- xviii) Ethanol (95%)
- xix) Vortex mixture
- xx) Nose mask and hand gloves
- xxi) Markers for labeling
- xxii) Racks and ice buckets
- xxiii) Waste containers

Plate 2.7: Biological safety cabinet in BCSIR microbiology laboratory, Rajshahi

2.6.3.2. Preparation of culture media

The instant nutrient agar (Mikrobiologie) medium was weighed and then reconstituted with distilled water in the McCartney bottle according to specification (28g L⁻¹). It was then heated in a microwave oven to dissolve the agar until a transparent solution was obtained. The bottle was plugged with cap and sterilized in an autoclave at 121°C and 15lbs/sq inch pressure for 15min. After sterilization, the media transferred to Petri dishes kept in for solidification. These were then preserved in refrigerator at 4°C for further studies.

2.6.3.3. Isolation of single colony of bacteria from effluent

Effluent samples were serially diluted in sterile distilled water. Then 0.1ml of each effluent sample was taken in eppendrof tube then 0.9ml distilled water added and carefully shaken on a vortex mixture for few min. This solution was then serially diluted to the 10⁻⁷ dilution, from which 0.1ml was separately plated onto nutrient agar medium and then incubated for 24 to 48h at 37°C. Discrete bacterial colonies that developed on agar plates were initially grouped on the basis of colony morphology. Selected bacterial isolates were further purified and sub-cultured. The pure cultures were identified based on gram staining and motility followed by their biochemical activities.

Gram stain: The stain makes use of the differing membrane structures between Gram positive and Gram negative organisms. The three stains (crystal violet, iodine solution and safranin) are used for this technique.

Procedure:

- The clean slide is taken and three drops of sterilized distilled water is dropped on three different places of the slide. A loop-full of isolate bacterial colonies are transferred with a sterilized loop one of the drop of distilled water on the slide and a very thin film is prepared by spreading uniformly. Then the loop is sterilized. A loop-full of bacterium is transferred from middle of the smear to the next water drop and thin film is prepared. In the same way bacterium is transferred from second to the third drop and thin film is prepared. This technique is better observation of each isolated bacterium. The film is fixed by passing it over the gentle flame for two or three times.

- Gently flood smears with crystal violet and let stand for 1min.
- Gently wash with tap water.
- Gently flood smears with the iodine solution and let stand for 1min.
- Gently wash with tap water.
- Decolorize with 95% ethyl alcohol. Do not over- decolorize. Add reagent drop by drop until alcohol runs almost clear, showing only a blue tinge.
- Gently wash with tap water.
- Counterstained with safranin for 45sec.
- Gently wash with tap water and blot dry with bibulous paper.
- At last the bacterial slide is examined under microscope.
- Gram positive cells will incorporate little or no counterstain and will remain blue-violet in appearance. Gram negative bacteria, however, take on a pink color and are easily distinguishable from the Gram positives.

Motility test: SIM (Sulfur Indole Motility Media) agar may also be used to detect motile organisms. Motility is recognized when culture growth (turbidity) of flagellated organisms is not restricted to the line of inoculation. Growth of non-motile organisms is confined to the line of inoculation. SIM tubes are inoculated with a single stab to the bottom of the tube and incubated at the 37°C temperature for 24 to 48h. If an organism is motile then the growth will radiate from the stab mark and make the entire tube appear turbid.

2.6.3.4. Maintenance of stock culture

The stock culture was maintained following the procedures of Carter (1979). Nutrient agar slants used for the maintenance of culture for each of the bacterial isolate. After growth of the organism in the slant, the sterile mineral oil was overlaid and culture was kept at room temperature for use as seed.

2.6.4. Biochemical analyses

Isolates were biochemically analyzed by; growth on MacConkey Agar and Mannitol salt agar; H₂S production test, Gelatin liquefaction test, Citrate utilization test, Urease test, Indole production test, MR-VP test, Catalase test, Amylase test, Triple Sugar Iron Agar test and Carbohydrate fermentation test. The tests were used to identify the

isolates according to Bergey's Manual of Determinative bacteriology (Holt *et al.*, 1994).

2.6.4.1. MacConkey agar test

MacConkey agar is a widely used culture medium that is both selective and differential. A selective medium selects for the growth of some organisms, while inhibiting the growth of others. In the case of MacConkey agar, the presence of bile salts and crystal violet inhibits the growth of most Gram positive bacteria. A differential medium does not inhibit the growth of bacteria, but differentiates them based on some visible growth characteristic such as colony color. MacConkey agar contains lactose, a fermentable carbohydrate, and the pH indicator neutral red. When lactose is fermented, acid products lower the pH below 6.8 with the resulting colonial growth turning pinkish-red. If an organism is unable to ferment lactose, the colonies will be colorless or yellow. The medium thus differentiates between lactose-fermenting bacteria and lactose non-fermenters, which include potential pathogens.

2.6.4.2. Hydrogen Sulfide Production test

Sulfur indole media (SIM) is a differential medium. It tests the ability of an organism to do several things: reduce sulfur, produce indole and swim through the agar (be motile). Sulfur can be reduced to H₂S (hydrogen sulfide) either by catabolism of the amino acid cysteine by the enzyme cysteine desulfurase or by reduction of thiosulfate in anaerobic respiration. If hydrogen sulfide is produced, a black color forms in the medium. The result is positive for H₂S production. Absence of the colour is evidence of a negative reaction.

2.6.4.3. Gelatin liquefaction test

This test is used to determine the ability of an organism to produce enzyme gelatinase, which liquefies gelatin. Gelatinase breaks down large proteins into smaller components, which can then enter the organism and be metabolized. Stab gelatin with organism using a straight wire and incubate at 37°C temperature for 24 to 48h. Place tubes in ice water bath for at least 30min. If gelatin is liquefied the result is positive. Gelatin is solid result is negative.

2.6.4.4. Citrate test

The test used to determine if an organism is capable of using citrate as the sole source of carbon with production of the enzyme citratase. The media contains sodium citrate as the carbon source, and ammonium salts as the nitrogen source, with bromthymol blue as the pH indicator. An organism that uses citrate breaks down the ammonium salts to ammonia, which creates an alkaline pH. Stab and streak Simmons citrate agar slant with the organism and incubate at the 37°C temperature for 24 to 48h. Alkaline pH causes media to change from green to Prussian blue the result is positive. For no color change the result is negative.

2.6.4.5. Urease test

This test used to determine the ability of an organism to split urea to form ammonia (an alkaline end product) by the action of the enzyme urease. Media also contains the pH indicator phenol red, which turns an intense pink at alkaline pH. Inoculate urea broth with the organism at 37°C temperature for 48h. After incubation phenol red turns to a deep pink color. This is a positive reaction for the presence of urease. Failure of the pink color is the result of negative reaction.

2.6.4.6. Indole test

This test used to determine the ability of an organism to split indole from the amino acid tryptophan using the enzyme tryptophanase. Incubate broth at 37°C temperature with the organism for 24 to 48h. Add 10 to 12 drops of Kovacs Reagent. Red layer forms on surface of the media the result is positive. If yellow layer forms on the surface of the media the result is negative.

2.6.4.7. MR-VP test

Methyl Red test (MR): Used the test to determine the ability of an organism to produce mixed acid end products from glucose fermentations. Some organisms produce large amounts of various acids (lactic, acetic, succinic, formic) plus H₂ and CO₂. The large amounts of acids lower the pH to lower than 5. Inoculate MR broths with these organisms at 37°C temperature for 24 to 48hours. After incubation add 3 to 4 drops of Methyl Red reagent to each tube. Red color develops for positive and yellow color develops for negative reaction.

Voges-Proskauer test (VP): The test used to determine the ability of an organism to produce acetoin; 2,3 butanediol; and ethanol which causes less lowering of the *pH* than the methyl red positive organisms. VP test detects the presence of acetoin, which is a precursor to 2,3 butanediol. Inoculate VP broths with these organisms at 37°C temperature for 24-48 hours. After incubation add 18 drops of Barritt's Solution A (alphanaphthol) and 18 drops of Barritt's Solution B (KOH). Agitate vigorously for 1 to 2min. Let stand for 1 to 2h. Positive reaction for wine red (burgundy) color develops and negative for brown color develops

2.6.4.8. Mannitol Salt Agar test (MSA)

This type of medium is both selective and differential. The MSA will select for organisms which can live in areas of high salt concentration. The differential ingredient in MSA is the sugar mannitol. Organisms capable of using mannitol as a food source will produce acidic byproducts of fermentation that will lower the *pH* of the media. The acidity of the media will cause the *pH* indicator, phenol red, to turn yellow.

2.6.4.9. Catalase test

This test is used to identify organisms that produce the enzyme catalase. This enzyme detoxifies hydrogen peroxide by breaking it down into water and oxygen gas. Streak nutrient agar plate with the organism and incubate at 37°C temperature for 24 to 48h. Add a few drops of 3% H₂O₂ on the colony, it is broken down and the oxygen produce bubbles. The bubbles resulting from production of oxygen gas clearly indicate a catalase positive and no bubbles indicate catalase negative.

2.6.4.10. Amaylase test

The test used to determine the ability of an organism to hydrolyze (break down) starch. The enzyme amylase breaks starch down into components more easily metabolized by the organism. Make a single streak of the organism on a starch agar plate and incubate at 37°C temperature for 24 to 48h. Drop a small amount of IKI (Gram's Iodine) onto the plate and rotate the plate gently. Iodine is an indicator of starch; in the presence of starch the iodine will turn blue/black. If positive, a zone of clearing appears adjacent to the streak line and negative no clearing; only a blue/black area surrounding the streak line.

2.6.4.11. Triple Sugar Iron (TSI) Agar test

Triple Sugar Iron Agar is used for the differentiation of microorganisms on the basis of dextrose, lactose, and sucrose fermentation and hydrogen sulfide production. Inoculate the TSI slant by first stabbing the butt down to the bottom, withdraw the needle, and then streak the surface of the slant. Use a loosely fitting closure to permit access of air. Incubate at 37°C for 18 to 24h. After incubation observe the color and gas production.

An alkaline slant-acid butt (red/yellow) indicates fermentation of dextrose only. An acid slant-acid butt (yellow/yellow) indicates fermentation of dextrose, lactose and/or sucrose. An alkaline slant-alkaline butt (red/red) indicates dextrose or lactose were not fermented (non-fermenter). Cracks, splits, or bubbles in medium indicate gas production. A black precipitate in butt indicates hydrogen sulfide production.

2.6.4.12. Carbohydrate fermentation test

The test used to determine the ability of an organism to ferment a specific carbohydrate with or without the production of gas. The carbohydrates test was performed by inoculating a loop-full organism into the tubes containing different sugar media and incubated for 24h at 37°C. Phenol Red is used as an indicator in the media. At a neutral pH, the media is red; at a pH of less than 7, the media is yellow. Fermentation of the carbohydrate produces acid, causing the media to change from red to yellow.

- 3.4. Antibacterial activities of the test extracts
- 3.5. Summary of the experimentation

Chapter 3

Results

3.1. Bioassay on *T. castaneum* adults

3.1.1. Effect of *C. papaya* extracts against *T. castaneum* adults by residual film assay

The Pet.E., CHCl₃ and CH₃OH extracts of *C. papaya* leaf, stem and roots were tested against the adult beetles of *T. castaneum* through residual film assay. For the final application the doses were ranged between 4.076 to 0.127mg cm⁻² where the test insects were released to observe mortality or any sort of behavioral changes due to the action of the extracts compared to their controls. To trace acute toxicity an observation of mortality was made after ½h of application of doses, followed by 12h of intervals up to 48h. The data was subjected to probit analysis and the results have been presented in Tables 3.1 to 3.2 and Appendix Tables I-XXXIV.

The Pet.E. extract of *C. papaya* leaf, stem and roots showed mortality to the adult beetles of *T. castaneum* by giving the LD₅₀ values 1.202, 0.956, 0.891, 0.750 and 0.559mg cm⁻²; 1.636, 1.279, 0.980, 0.856 and 0.725mg cm⁻²; 2.336, 1.422, 0.853, 0.634 and 0.532mg cm⁻² for 6, 12, 24, 36 and 48h of exposure respectively. For the CHCl₃ extracts of stem the LD₅₀ values were 0.105, 4.745, 3.719, 2.759 and 2.053 mg cm⁻² for 6, 12, 24, 36 and 48h of exposure respectively while, the CHCl₃ extracts of leaf and root didn't offer any mortality to the beetles. For the CH₃OH extracts of leaf the LD₅₀ values were 3.640, 1.562, 0.861, 0.607 and 0.419mg cm⁻² for 6, 12, 24, 36 and 48h of exposure respectively; followed by the stem and root extract with the LD₅₀ values 2.026, 0.945, 0.573, 0.343 and 0.274mg cm⁻²; 0.878, 0.414, 0.188, 0.129 and 0.114mg cm⁻² for the same exposure respectively.

The highest and the lowest mortality have been observed for the CH₃OH extract of root (LD₅₀ 0.114mg cm⁻²) and CHCl₃ extracts of stem (LD₅₀ 2.053mg cm⁻²) after 48h of exposure respectively. Observation after ½h assured acute toxicity positively, however, the LD₅₀ values was simply larger.

According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl_3 and CH_3OH extracts could be arranged in a descending order: root (CH_3OH) > stem (CH_3OH) > leaf (CH_3OH) > root (Pet.E.) > leaf (Pet.E.) > stem (Pet.E.) > stem (CHCl_3) extract.

Table 3.1: LD_{50} values, 95% confidence limits, regression equations and χ^2 values (along with their df) of the Pet.E. extracts of *C. papaya* leaf, stem and roots against *T. castaneum* adults

| Solvent | Plant organs | Exposure (h) | LD_{50} (mg cm^{-2}) | 95% confidence limits | | Regression equations | χ^2 values (df) |
|---------|--------------|---------------|---|-----------------------|-------|-----------------------|----------------------|
| | | | | Lower | Upper | | |
| Pet.E. | Leaf | $\frac{1}{2}$ | - | - | - | - | - |

3.1.2. Effect of *M. oliefera* extracts against *T. castaneum* adults by residual film assay

The Pet.E., CHCl₃ and CH₃OH extracts of *M. oliefera* fruit, leaf, stem bark, stem wood, root bark and root wood were tested against the adult beetles of *T. castaneum* through residual film assay. For the final application doses were ranged between 2.038 to 0.764mg cm⁻² where the test insects were released to observe mortality or any sort of behavioral changes due to the action of the extracts compared to their controls. To trace acute toxicity an observation of mortality was made after ½h of application of doses and followed by 12h intervals up to 48h. The data was subjected to probit analysis and the results have been presented in Tables 3.3 to 3.4 and Appendix Tables XXXV-LXXVII.

The Pet.E. extract of *M. oliefera* stem bark, root bark and root woods showed mortality to the adult beetles of *T. castaneum* by giving the LD₅₀ values 2.022, 1.055, 0.812, 0.628 and 0.466mg cm⁻²; 0.812, 0.610, 0.536, 0.427 and 0.365mg cm⁻²; 3.142, 2.041, 1.489, 0.983 and 0.629mg cm⁻² for 6, 12, 24, 36 and 48h of exposure respectively. Root bark Pet.E. extract showed acute toxicity by giving LD₅₀ 1.888mg cm⁻² after ½h of exposure. For the CH₃OH extract of fruit, stem bark, stem wood, root bark and root wood the LD₅₀ values were 0.859, 0.606, 0.436, 0.420 and 0.382mg cm⁻²; 1.379, 0.786, 0.519, 0.392 and 0.308mg cm⁻²; 1.568, 1.350, 1.005, 0.691 and 0.535mg cm⁻²; 0.757, 0.552, 0.403, 0.312 and 0.276mg cm⁻²; 1.017, 0.847, 0.617, 0.474 and 0.393mg cm⁻² for 6, 12, 24, 36 and 48h of exposure respectively. Fruit and stem wood CH₃OH extract showed acute toxicity by giving LD₅₀ 2.754 and 5.044mg cm⁻² after ½h of exposure respectively. The highest and the lowest mortality have been observed for the CH₃OH extract of root bark (LD₅₀ 0.276mg cm⁻²) and Pet.E. extracts of root wood (LD₅₀ 0.629mg cm⁻²) after 48h of exposure respectively.

To consider acute toxicity of the extracts a reading of data is made after ½h of exposure, and in this case the result was positive, while the LD₅₀ values were comparatively larger. It is of course mentionable that the other test materials, viz. the Pet.E. extracts of fruit, leaf, stem wood; CHCl₃ extracts of fruit, leaf, stem bark, stem wood, root bark, root wood and CH₃OH extracts of the leaf of *M. oliefera* didn't show any mortality against the adult beetles of *T. castaneum*.

According to the intensity of activity observed through mortality of the adult beetles the potentiality of the Pet.E. and methanol extracts could be arranged in a descending order: root bark (CH₃OH) > stem bark (CH₃OH) > root bark (Pet.E.) > fruit (CH₃OH) > root wood (CH₃OH) > stem bark (Pet.E.) > stem wood (CH₃OH) > root wood (Pet.E.) extract.

Table 3.3: LD₅₀ values, 95% confidence limits, regression equations and χ^2 values (along with their df) of the Pet.E. extracts of *M. oliefera* stem bark, root bark and root woods against *T. castaneum* adults

3.1.3. Effect of *Mu. sapientum* extracts against *T. castaneum* adults by residual film assay

The Pet.E., CHCl₃ and CH₃OH extracts of *Mu. sapientum* leaf, stem and roots were tested against the adult beetles of *T. castaneum* through residual film assay. For the final application doses were ranged between 2.038 to 0.127mg cm⁻² where the test insects were released to observe mortality or any sort of behavioral changes due to the action of the extracts compared to their controls. To trace acute toxicity an observation of mortality was made after ½h of application of doses and followed by 12h of intervals up to 48 hours. The data was subjected to probit analysis and the results have been presented in Tables 3.5 to 3.6 and Appendix Tables LXXVIII-CV.

The Pet.E. extract of *Mu. sapientum* leaf, stem and roots showed mortality to the adult beetles of *T. castaneum* by giving the LD₅₀ values 4.134, 2.865, 1.899, 1.489 and 1.195mg cm⁻²; 1.282, 1.009, 0.814, 0.751 and 0.582mg cm⁻²; 2.359, 1.568, 1.177, 0.849 and 0.718mg cm⁻² for 6, 12, 24, 36 and 48h of exposure respectively. Pet.E. stem extracts showed acute toxicity by giving LD₅₀ 9.289mg cm⁻² after ½h of exposure. For the CH₃OH extract of leaf, stem and root the LD₅₀ values were 3.018, 1.804, 0.627 and 0.213 mg cm⁻²; 0.646, 0.318, 0.204 and 0.163mg cm⁻²; 1.935, 0.413, 0.073 and 0.205mg cm⁻² for 12, 24, 36 and 48h of exposure respectively. The highest and the lowest mortality have been observed for the CH₃OH extract of stem (LD₅₀ 0.163mg cm⁻²) and Pet.E. extracts of leaf (LD₅₀ 1.195mg cm⁻²) after 48h of exposure respectively.

To consider acute toxicity of the extracts a reading of data was made after ½h of exposure, and in this case the result was positive, while the LD₅₀ values were comparatively larger. It is of course mentionable that the other test materials, viz. the CHCl₃ extracts of leaf, stem and roots of *Mu. sapientum* didn't show any mortality against the adult beetles of *T. castaneum*.

According to the intensity of activity observed through mortality of the adult beetles the potentiality of the extracts could be arranged in a descending order: stem (CH₃OH) > root (CH₃OH) > leaf (CH₃OH) > stem (Pet.E.) > root (Pet.E.) > leaf (Pet.E.) extract.

Table 3.5: LD₅₀ values, 95% confidence limits, regression equations and χ^2 values (along with their df) of the Pet.E. extracts of *Mu. sapientum* leaf, stem and roots against *T. castaneum* adults

| Solvent | Plant organs | Exposure (h) | LD ₅₀ (mg cm ⁻²) | 95% confidence limits | | Regression equations | χ^2 values (df) |

3.2. Bioassay on *A. salina* nauplii

3.2.1. Lethal effect of *C. papaya* extracts against *A. salina* nauplii

The Pet.E., CHCl_3 and CH_3OH extracts of *C. papaya* leaf, stem and roots were tested against the one day aged *A. salina* nauplii through lethality assay. For the final application selected doses were ranged between 250 to 6.25ppm where the nauplii were released to observe lethality or any sort of behavioral changes due to the action of the extracts compared to their controls. Observation of mortality was made after 6h of application of the doses followed by 6h intervals up to 24h. The data was subjected to probit analysis and the results have been presented in Tables 3.7 to 3.8 and Appendix Tables CVI-CXXXIX.

The Pet.E. extract of *C. papaya* leaf, stem and roots showed lethality to the *A. salina* nauplii by giving the LC_{50} values 4180.528, 1032.428, 363.954 and 102.701ppm; 3173.579, 115.180, 44.033 and 17.230ppm; 472.900, 187.898, 78.891 and 52.268ppm for 6, 12, 18 and 24h of exposure respectively. For the CHCl_3 extracts of leaf the LC_{50} values were 372.025, 98.248 and 1.326ppm for 12, 18 and 24h of exposure respectively; followed by the stem extract 129.233, 76.026, 37.335 and 14.689ppm for 6, 12, 18 and 24h of exposure respectively; and also followed by the root extract 257.124, 156.739 and 40.072ppm for 12, 18 and 24h of exposure respectively. For the CH_3OH extract of leaf, stem and roots the LC_{50} values were 1370.555, 2665.86, 467.792 and 183.443ppm; 72.337, 45.542, 31.059 and 29.593ppm; 33.176, 22.699, 20.559 and 14.402ppm for 6, 12, 18 and 24h of exposures respectively. The highest and the lowest mortality have been observed for the CHCl_3 extract of leaf (LC_{50} 1.326ppm) and CH_3OH extracts of leaf (LC_{50} 183.443ppm) after 24h of exposure respectively.

According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl_3 and CH_3OH extracts could be arranged in a descending order: leaf (CHCl_3) > root (CH_3OH) > stem (CHCl_3) > stem (Pet.E.) > stem (CH_3OH) > root (CHCl_3) > root (Pet.E.) > leaf (Pet.E.) > leaf (CH_3OH) extract.

Table 3.7: LC₅₀ values, 95% confidence limits, regression equations and χ^2 values (along with their df) of the Pet.E. extracts of *C. papaya* leaf, stem and root against *A. salina* nauplii

3.2.2. Lethal effect of *M. oleifera* extracts against *A. salina* nauplii

The Pet.E., CHCl₃ and CH₃OH extracts of *M. oleifera* fruit, leaf, stem bark, stem wood, root bark and root wood were tested against the one day aged *A. salina* nauplii through lethality assay. For the final application doses were ranged between 300 to 1.563ppm where the nauplii were released to observe lethality or any sort of behavioral changes due to action of the extracts compared to their controls. Observation of mortality was made after 6h of application of doses followed by 6h intervals up to 24h. The data was subjected to probit analysis and the results have been presented in Tables 3.9 to 3.11 and Appendix Tables CXL -CCI.

The Pet.E. extract of *M. oleifera* fruit, leaf and root woods showed lethality to the *A. salina* nauplii by giving the LC₅₀ values 81.213, 64.503, 61.055 and 58.228ppm; 562.916, 264.065, 228.101 and 123.482ppm and 103.841, 101.871, 90.784 and 78.393ppm for 6, 12, 18 and 24h of exposures respectively; followed by the stem wood and root bark extracts 72.589, 66.061 and 52.857ppm; 87.223, 76.028 and 68.485ppm for 12, 18 and 24h of exposure respectively. For the CHCl₃ extracts of fruit, stem bark, stem wood, root bark and root wood the LC₅₀ values were 237.446, 128.977, 87.433 and 70.318ppm; 83.813, 84.075, 65.847 and 54.301ppm; 55.125, 35.967, 31.297 and 24.774ppm; 131.175, 85.637, 13.549 and 4.197ppm; 1075.790, 5437.378, 131.251 and 42.595ppm for 6, 12, 18 and 24h of exposure respectively. For the CH₃OH extract of fruit, leaf, stem bark, stem wood, root bark and root wood the LC₅₀ values were 1871.084, 442.596, 174.437 and 98.856ppm; 832.692, 491.176, 323.301 and 234.246ppm; 629.882, 351.887, 182.040 and 110.484ppm; 1368.165, 644.586, 51.143 and 35.876ppm; 139.280, 87.429, 44.824 and 24.119ppm; 3906.864, 941.192, 326.569 and 178.993ppm for 6, 12, 18 and 24h of exposure respectively. The highest and the lowest mortality have been observed for the CHCl₃ extract of root bark (LC₅₀ 4.197ppm) and CH₃OH extracts of leaf (LC₅₀ 234.246ppm) after 24h of exposure respectively.

It is of course mentionable that the other test materials, viz. the Pet.E. extracts of stem bark didn't show proper activity and CHCl_3 extracts of *M. oliefera* leaf didn't show any activity against the nauplii of *A. salina*. The Pet.E. extracts of *M. oliefera* stem bark was sticky and it could not dissolve in water properly.

According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl_3 and CH_3OH extracts could be arranged in a descending order: root bark (CHCl_3) > root bark (CH_3OH) > stem wood (CHCl_3) > stem wood (CH_3OH) > root wood (CHCl_3) > stem wood (Pet.E.) > stem bark (CHCl_3) > fruit (Pet.E.) > root bark (Pet.E.) > fruit (CHCl_3) > root wood (Pet.E.) > fruit (CH_3OH) > stem bark (CH_3OH) > leaf (Pet.E.) > root wood (CH_3OH) > leaf (CH_3OH) extract.

.

Table 3.9: LC₅₀ values, 95% confidence limits, regression equations and χ^2 values (along with their df) of the Pet.E. extracts of *M. oleifera* fruit, leaf, stem wood, root bark and root woods against *A. salina* nauplii

3.2.3. Lethal effect of *Mu. sapientum* of extracts against *A. salina* nauplii

The Pet.E., CHCl₃ and CH₃OH extracts of *Mu. sapientum* leaf, stem and roots were tested against the one day aged *A. salina* nauplii through lethality assay. For the final application doses were ranged between 200 to 6.25ppm where the nauplii were released to observe lethality or any sort of behavioral change due to the action of the extracts compared to their controls. Observation of mortality was made after 6h of application of the doses and followed by 12h of intervals up to 24h. The data was subjected to probit analysis and the results have been presented in Table 3.12 to 3.13 and Appendix Table CCII-CCXXXVII.

The Pet.E. extract of *Mu. sapientum* leaf, stem and roots showed lethality to the *A. salina* nauplii by giving the LC₅₀ values 451.924, 228.629, 186.776 and 127.604ppm; 156.611, 82.246, 75.313 and 53.893ppm; 101.402, 72.270, 60.274 and 50.018ppm for 6, 12, 18 and 24h of exposure respectively. For the CHCl₃ extracts of leaf, stem and root the LC₅₀ values were 178.457, 69.203, 42.582 and 29.951ppm; 508.222, 177.202, 75.989 and 37.456ppm; 85.551, 76.793, 63.219 and 55.624ppm for 6, 12, 18 and 24h of exposure respectively. For the CH₃OH extract of leaf, stem and roots the LC₅₀ values were 159.309, 71.492, 36.238 and 22.991ppm; 218.929, 496.210, 444.961 and 117.196ppm; 136.148, 121.240, 111.449 and 101.977ppm for 6, 12, 18 and 24h of exposure respectively.

The highest and the lowest mortality have been observed for the CH₃OH extract of leaf bark (LC₅₀ 22.991ppm) and Pet.E. extracts of leaf (LC₅₀ 127.604ppm) after 24h of exposure respectively.

According to the intensity of activity observed through dose mortality test against the adult beetles the potentiality of the Pet.E., CHCl₃ and CH₃OH extracts could be arranged in a descending order: leaf (CH₃OH) > leaf (CHCl₃) > stem (CHCl₃) > root (Pet.E.) > stem (Pet.E.) > root (CHCl₃) > root (CH₃OH) > stem (CH₃OH) > leaf (Pet.E.) extract.

3.3. Isolation of bacteria from industrial effluent

Bacterial strains were isolated from industrial (tannery) effluent. Fifteen colonies were screened from initial level of effluent on nutrient agar media. Out of fifteen colonies, nine isolates were selected for biochemical test and other studies (Table 3.14a to 3.14b). From the selected isolates two isolates were from sample 1 (Isolate 1 and 2), four from sample 2 (Isolate 3, 4, 5 and 6) and three from sample 3 (Isolate 7, 8 and 9). The rest of the isolates were rejected for their same colony characteristics.

3.3.1. Physico-chemical analysis of industrial effluent samples

The collected samples were analyzed in the laboratory of the Bangladesh Council of Scientific and Industrial Research (BCSIR), Dhaka and the Central Laboratory, University of Rajshahi, Bangladesh. The results are presented in the Table 3.15 and in Appendix (page, LXXXI – LXXXV).

Table 3.15: Physico–chemical characteristics of industrial effluent

| SI. No. | Parameters | Results | | |
|---------|--------------------------|-----------|-----------|-----------|

3.4. Antibacterial activities of the test extracts

The Pet.E., CHCl₃ and CH₃OH extract of *C. papaya* (leaf, stem and root), *M. oliefera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) were tested against 7 selected bacteria (2 Gram- positive bacteria *Bacillus subtilis*, *Staphylococcus aureus* and 5 Gram negative bacteria *Escherichia coli*, *Klebsiella pneumoniae*, *Salmonella enteritidis*, *Shigella flexneri* and *Shigella sonnei*) to evaluate their antibacterial potential at concentrations of 200 and 400µg disc⁻¹ along with a standard antibiotic, Ampicillin 10µg disc⁻¹, 9 isolates (from industrial effluent) at a concentration 400µg disc⁻¹ along with a standard antibiotic, Kanamycin 30µg disc⁻¹. The results obtained are shown in Tables 3.16 to 3.20.

3.4.1. Antibacterial activity against the selected bacteria

3.4.1.1. Antibacterial activity of the *C. papaya* extracts

Among the *C. papaya* extracts the root extracts showed the highest antibacterial activity. Only the *B. subtilis*, *K. pneumoniae* and *St. aureus* were responsive among the selected test bacteria.

St. aureus was most susceptible against all three types of extracts by showing the inhibition zone of 9mm (leaf Pet.E.), 10mm (stem CHCl₃), 15mm (root Pet.E.) and 10mm (root CH₃OH) for 400µg disc⁻¹ application. While, *B. subtilis* only susceptible against the root CHCl₃ and *K. pneumoniae* against the stem CHCl₃ extracts by showing the inhibition zone of 20 and 9mm respectively for 400µg disc⁻¹ application.

B. subtilis, *K. pneumoniae* and *St. aureus* showed 40, 40 and 38mm inhibition zones for the standard Ampicillin 10µg disc⁻¹ respectively. While, *Sh. flexneri* and *Sh. sonnei* were not responsive against the extracts but they were responsive for the standard Ampicillin with the inhibition zone of 28 and 38mm respectively while, *E. coli* and *S. enteritidis* did not responsive for both the doses and standard Ampicillin. All the bacteria were not responsive against 200µg disc⁻¹ application.

Plate 3.19: Antibacterial activity test of *M. oleifera* extracts against *K. pneumoniae* for 400µg disc⁻¹ application along with standard Ampicillin 10µg disc⁻¹

3.4.1.2. Antibacterial activity of the *M. oleifera* extracts

Among the *M. oleifera* extracts stem wood extracts showed the highest antibacterial activity. Only *B. subtilis*, *K. pneumoniae* and *St. aureus* were responsive among the selected test bacteria.

St. aureus was most susceptible against all six types of extracts by showing the inhibition zones of 10mm (fruit Pet.E.), 9mm (fruit CHCl₃), 9mm (leaf Pet.E.), 9mm (stem bark Pet.E.), 10mm (stem bark CHCl₃), 10mm (stem wood CHCl₃), 12mm (stem wood CH₃OH), 11mm (root bark Pet.E.), 9mm (root bark CHCl₃) and 10mm (root wood CHCl₃) for 400µg disc⁻¹ application. *B. subtilis* was susceptible against the fruit Pet.E. and stem bark CHCl₃ extracts by showing the inhibition zone of 9mm each for 400µg disc⁻¹ application and *K. pneumoniae* against the fruit CHCl₃ and stem wood CHCl₃ extracts by showing the inhibition zone of 11 and 10mm respectively for 400µg disc⁻¹ application.

B. subtilis, *K. pneumoniae* and *St. aureus* showed 40, 45 and 38mm inhibition zones for the standard Ampicillin 10µg disc⁻¹ respectively. While, *Sh. flexneri* and *Sh. sonnei* were not responsive against the extracts but they were responsive for the standard Ampicillin with the inhibition zone of 28 and 37mm respectively while, *E. coli* and *S. enteritidis* did not responsive for both the doses and standard Ampicillin. All the bacteria were not responsive against 200µg disc⁻¹ application.

[Zone of inhibition in mm]

3.4.1.3. Antibacterial activity of the *Mu. sapientum* extracts

Among the *Mu. sapientum* extracts the root extracts showed the highest antibacterial activity. Only the *St. aureus* was responsive among the selected test bacteria.

St. aureus was susceptible against stem (Pet.E.) and root (Pet.E.) extracts by showing the inhibition zone of 8 and 10mm for 400µg disc⁻¹ application and also susceptible to the standard Ampicillin 10µg disc⁻¹ with an inhibition zone of 30mm.

B. subtilis, *K. pneumonia*, *Sh. flexneri* and *Sh. sonnei* were not responsive against the extracts but they were responsive for the standard Ampicillin with the inhibition zone of 40, 40, 28 and 37mm respectively. While, *E. coli* and *S. enteritidis* did not responsive for both the doses and standard Ampicillin. All the bacteria were not responsive to 200µg disc⁻¹ application.

Strain of *St. aureus* on *Mu. sapientum* (root) extracted in Pet.E. for 200 and 400µg disc⁻¹

3.4.2. Antibacterial activity against the isolates from the effluent

The Pet.E., CHCl_3 and CH_3OH extract of *C. papaya* (leaf, stem and root), *M. oliefera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) were tested against 9 isolates viz. Isolate 1 (*Bacillus cereus*), Isolate 2 (*Klebsiella oxytoca*), Isolate 3 (*Staphylococcus aureus*), Isolate 4 and 5 (*Escherichia coli*), Isolate 6 (*Citrobacter freundii*), Isolate 7 (*Proteus vulgaris*), Isolate 8 (*Bacillus subtilis*) and Isolate 9 *Salmonella typhimurium* at a concentrations of $400\mu\text{g disc}^{-1}$ doses. Kanamycin $30\mu\text{g disc}^{-1}$ is used as the standard antibiotic. The results obtained are shown in Tables 3.28.

Among the 9 Isolates Isolate 8 *Bacillus subtilis* was highly responsive to the Pet.E. and CHCl_3 extracts of *C. papaya* stem (15 & 08mm), *M. oliefera* fruit (14 & 09mm) and root bark (10 & 16mm), and *Mu. sapientum* root (10 & 10mm) respectively; to the Pet.E. extracts of *C. papaya* root (11mm), *M. oliefera* root wood (11mm), *Mu. sapientum* stem (10mm), and to the CHCl_3 extract of *M. oliefera* stem bark (08mm). Next to the Isolate 8 it was Isolate 2 *Klebsiella oxytoca* responsive to the Pet.E. extracts of *C. papaya* leaf (08mm), *M. oliefera* fruit (08mm), *Mu. sapientum* leaf (15mm) and root (10mm); and to the CHCl_3 extract of *C. papaya* leaf (08mm), *M. oliefera* stem bark (08mm), stem wood (08mm) and root bark (08mm); followed by the Isolate 1 *Bacillus cereus* which was responsive to the Pet.E. extracts of *C. papaya* stem (16mm), *M. oliefera* fruit (10mm) and *Mu. sapientum* stem (8mm) and root (10mm); this was followed by Isolate 3 *Staphylococcus aureus* which was responsive to the Pet.E. extracts of *C. papaya* stem (10mm), *M. oliefera* fruit (13mm) and *Mu. sapientum* root (08mm) and again the CHCl_3 extract of *M. oliefera* stem bark (08mm). This was followed by the Isolate 6 *Citrobacter freundii* where CHCl_3 extract of *C. papaya* stem (08mm) and Pet.E. extract of *Mu. sapientum* leaf (10mm) were found responsive. Isolate 4 and 5 *Escherichia coli* and 9 *Salmonella typhimurium* show response against Pet.E. extracts of *C. papaya* stem (08mm), *M. iloefera* fruit (08mm) and CHCl_3 extract of *M. oliefera* stem wood (09mm) respectively. Isolate 7 *Proteus vulgaris* was not responsive to any of the 12 extracts of the 3 test plants. For Kanamycin $30\mu\text{g disc}^{-1}$ the inhibition zones for the Isolate 1, 2, 3, 4, 5, 6, 7, 8 and 9 were 50, 35, 35, 40, 36, 42, 42, 55 and 40mm respectively.

Table 3.20: Antibacterial activity of *C. papaya*, *M. oleifera* and *Mu. sapientum* extracts against nine isolates for 400µg disc⁻¹ application

3.5. Summary of the experimentation

For the detection of bioactive potentials of *C. papaya* (leaf, stem and root), *M. oleifera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) extracted in Pet.E., CHCl₃ and CH₃OH solvents insecticidal, brine shrimp lethality and antibacterial activity tests have been carried out. A total outcome of the bioassays carried out is represented in the Table 3.21 to 3.23 given below:

Table 3.21: Result summary of *C. papaya* extracts

| C. papaya | | | Plant | | | | | | | | | | | | | | | |

Chapter 4

Discussion

Plants known as bionormalizers viz. *Carica papaya* Linn., *Moringa oleifera* Lam. and *Musa sapientum* L. were taken into consideration to determine whether or not materials of these plants affecting biodegrading bacteria that take part in normalization of industrial effluent. The Pet.E., CHCl₃ and CH₃OH extracts of *C. papaya* (leaf, stem and root), *M. oleifera* (fruit, leaf, stem bark, stem wood, root bark and root wood) and *Mu. sapientum* (leaf, stem and root) were the test materials. The title experiments were carried out against the bacterial isolates (9 isolates found in collected tannery effluent were determined as 1. *Bacillus cereus*, 2. *Klebsiella oxytoca*, 3. *Staphylococcus aureus*, 4. *Escherichia coli* (I), 5. *Escherichia coli* (II), 6. *Citrobacter freundii*, 7. *Proteus vulgaris*, 8. *Bacillus subtilis*, 9. *Salmonella typhimurium*). A parallel supporting experiment was also set against 7 bacteria (2 Gram- positive bacteria *B. subtilis*, *St. aureus* and 5 Gram negative bacteria *E. coli*, *K. pneumoniae*, *Sa. enteritidis*, *S. flexneri* and *S. sonnei* which were available in the laboratory of IES, RU. Physico-chemical characteristics of the tannery effluent were also determined along with the characterization of the found bacterial isolates to have a complete knowledge on the effluent and its functional relationship with the bacteria to be certain whether or not they play a role in biodegradation. Besides, potentiation of the test plants were done through insecticidal activity test against the red flour beetle, *Tribolium castaneum* (Hbst.) through dose-mortality assay, and against the brine shrimp, *Artemia salina* L. nauplii through cytotoxicity test. The results were found promising in terms of causing less harm to the biodegrading bacteria, while it is popularly known that the test plants themselves take part in bionormalization (Von Maydell, 1986).

The results receive supports from the results achieved by the previous researchers, however all the isolates found in the effluent may not be the same in their attributes to response against the extractives of the test plants, i.e. the bionormalizer plants.

For *C. papaya* Pet.E. extract of leaf found active against *St. aureus*, CHCl_3 extracts of stem found active against *St. aureus* and *K. pneumoniae*; and the Pet.E., CHCl_3 and CH_3OH extracts of roots were found active against *B. subtilis* and *St. aureus* among the 7 test bacteria (of IES laboratory) *B. subtilis*, *St. aureus*, *E. coli*, *K. pneumoniae*, *Sa. enteritidis*, *S. flexneri* and *S. sonnei*. Again, among the 9 isolates from the tannery effluent Pet.E. and CHCl_3 extracts of leaf showed activity against *K. oxytoca*; Pet.E. and CHCl_3 extracts of stem showed activity against *B. cereus*, *St. aureus*, *E. coli* (I), *Citrobacter freundii* and *B. subtilis*; Pet.E. extract of roots showed activity against *B. subtilis* only, however no activity was traced against *E. coli* (II), *P. vulgaris* and *Sa. typhimurium* at all.

Alabi *et al.* (2012) found aqueous, ethanol and acetone extracts of dried and fresh leaves of *C. papaya* not to show active against majority of almost 11 test bacteria: *E. coli* (3 strains), *K. pneumoniae*, *E. faecalis*, *S. aureus* (3 strains), *S. pyogenes*, *P. aeruginosa*, *K. oxytoca*, *P. vulgaris*. Among them only *S. aureus* was responsive at 50 and 100mg/ml of the aqueous extract of the dried leaves of *C. papaya*. The ethanol extract of the same didn't show any activity at doses 25 and 50mg/ml, and even at 100mg/ml *K. oxytoca* and 2 strains of *S. aureus* didn't response; while for the acetone extract *K. pneumoniae*, *E. faecalis*, *E. coli* and *S. aureus* were responsive at 100mg/ml concentration. For the fresh leaf extract the scenario was more disappointing in terms of strong activity, where one strain of *S. aureus* found responsive to aqueous extract at 50 and 100mg/ml, 2 strains of *E. coli* and *K. oxytoca* were responsive for ethanol extract at only 100mg/ml concentration; while for the acetone extract of the same only *S. aureus* was responsive at 100mg/ml concentration. They also carried out another test experiment on the same extracts against 6 fungi *Epidermophyton floccosum*, *Aspergillus niger*, *Aspergillus flavus*, *Trichophyton metagrophytes*, *Candida albicans* and *Aspergillus carbonarius* for both dried and fresh leaf extracts for 25, 50 and 100mg/ml concentrations, and only three of them: *A. flavus*, *T. metagrophytes* and *C. albicans* were responsive at 100mg/ml of the aqueous extract with 2, 1 and 1 mm of inhibition zones respectively. The MIC was recorded with 100mg/ml concentration of most of the extracts against the bacteria and 3 fungi (Alabi *et al.*, 2012). Anibijuwon and Udeze (2009) showed the brown colored hot water extract of *C. papaya* leaf was

found active against *P. aeruginosa* while the ethanol and the methanol extracts were not active at all. Nirosha and Mangalanayaki (2013) tested leaf and root extracts of *C. papaya* against *E. coli*, *P. aeruginosa*, *S. typhi*, *S. aureus* and *B. subtilis* extracted in water, ethanol and ethyl acetate. They got no response for the water extracts, while at concentrations 100, 150, 200 and 250mg/ml the clear zones for ethanol and ethyl acetate extracts were not so much promising. Orhue and Momoh (2013) tested *C. papaya* seed, leaf and peel extracted in water, ethanol, 1% HCL, acetone and petroleum against the bacteria *S. aureus*, *E. coli* and *P. aeruginosa*, and got no response for the water extract. Peter *et al.* (2014) found a high dose (100mg/ml DMSO) of 70% methanolic and the aqueous extracts of *C. papaya* seeds to yield 3 and 2mm inhibition zones.

For *M. oleifera* Pet.E. extract of fruit was found active against *B. subtilis* and *St. aureus* and the CHCl_3 extract of the same was active against *St. aureus* and *K. pneumoniae*; the Pet.E. extract of leaf was active against *St. aureus*. While the Pet.E. and CHCl_3 extracts of stem bark were active against *B. subtilis* and *St. aureus*. Pet.E., CHCl_3 and CH_3OH extracts of the stem wood were active against *St. aureus* and *K. pneumoniae*; Pet.E. and CHCl_3 extracts of the root bark and the CHCl_3 extract of the root wood found active only against *St. aureus*, and no activity was traced against *E. coli*, *Sa. enteritidis*, *Sh. flexneri* and *Sh. sonnei*. Moreover, all the responses were achieved for $400\mu\text{g disc}^{-1}$ which is obviously a higher dose

Rockwood *et al.* (2013) tested leaf and seed extracts of *M. oleifera* against *B. spaericus*, *B. subtilis*, *B. megaterium*, *B. cereus*, *M. smegmatis*, *S. aureus*, *A. faecalis*, *E. aerogenes*, *E. coli*, *K. pneumoniae*, *P. mirabilis*, *P. vulgaris* and *S. flexneri* and they got only *B. spaericus* to response against the leaf extract and *B. spaericus*, *M. smegmatis*, *S. aureus*, *A. faecalis* to response against the seed extract; and it shows that *M. oleifera* leaf and seed extracts have no effect on *B. subtilis*, *B. megaterium*, *B. cereus*, *M. luteus*, *E. aerogenes*, *E. coli*, *K. pneumoniae*, *P. mirabilis*, *P. vulgaris* and *S. flexneri*. Singh (2013) revealed that aqueous, hexane, ethanol and methanol extracts of *M. oleifera* leaf gave inhibition zones against *P. aeruginosa*, *S. aureus* and *E. coli*, however there were some 7, 8, and 9mm diam. clear zones which are negligible in terms of strength of activity where the disc used was 6mm in diam. Patil and Jane (2013) carried out a test

of methanol, petroleum ether acetone and chloroform extracts of the roots of *M. oleifera* on sensitivity of otitis media pathogens *K. pneumoniae*, *S. aureus*, *P. aeruginosa* and *S. pneumoniae* and the results showed that the petroleum ether and chloroform extracts had no effect on all the test bacteria, and the methanol extract didn't inhibit *K. pneumoniae* and *S. aureus*; and the acetone extract didn't inhibit *P. aeruginosa* and *S. pneumoniae*. For *S. pneumoniae* and *E. coli* the MIC were 16mg/ml, however, high MIC may be an indication of low efficacy or that the organisms have the potential for developing resistance to the bioactive compounds (Anibijuwon and Udeze, 2009). Onsare *et al.* (2013) found that aqueous extracts of seeds and seeds kernel of *M. oleifera* were active against a number of bacteria except *S. flexeneri*, *S. typhimurium* and *E. coli*.

For *Mu. sapientum* Pet.E. extracts of stem and root showed activity against *St. aureus* both for 400µg disc⁻¹ among the 7 test bacteria, and Pet.E. extracts of leaf, stem and roots found active against *K. oxytoca* and *Citrobacter freundii*, *B. cereus* and *St. aureus*, and *B. cereus*, *K. oxytoca*, *St. aureus* and *B. subtilis* respectively; while the CHCl₃ extracts of the root also found active against *B. subtilis* among the 9 isolates found in the tannery effluent. However, the *Mu. sapientum* extractives didn't show any activity against the 5 isolates, *i.e.* *E. coli* (I), *E. coli* (II), *Citrobacter freundii*, *P. vulgaris* and *Sa. typhimurium*.

Hashempour (2014) tested aqueous extract of *Mu. sapientum* on *Sa. typhimurium* and *C. albicans* and found that it inhibited the growth of the bacteria but couldn't stop growth of the fungus. Rashid and Sajid (2013) tested methanolic extract of *Mu. sapientum* to yield that the LD₅₀ must be bigger than 5000mg/kg body weight on mice. Venkatesh *et al.* (2013) found MIC 4mg/ml for *E. coli* which means this plant can hardly suppress the growth of *E. coli* with usual doses. The activity of *Mu. sapientum* extractives were more less similar to those of the results found in case of *C. papaya* and *M. oleifera*.

For further potentiation of the extractives insecticidal and brine shrimp lethality tests were also carried out as part of this investigation. Plants having medicinal value indicate occurrence of biopotential components in them, since curing disease means elimination of the causal agents of those diseases, *i.e.* the pathogenic bacteria, fungi,

virus, certain protozoans, helminthes, etc. However, all the 3 test plants are well known for their medicinal uses. Papaya the "medicine tree" or "melon of health" is filled with nutrients (Jackwheeler, 2003) and have antibacterial activity (Basile *et al.*, 1999), cure sickle cell diseases (Imaga, *et al.*, 2009) and poisoning related renal disorder (Olagunju, *et al.*, 2009), and also known as an anti-helminthes (Okeniyi *et al.*, 2007). It contains antifertility properties, particularly the seeds, (Lohiya *et al.*, 1999). A complete loss of fertility has been reported in male rabbits, rats and monkeys fed an extract of papaya seeds (Glazer and Smith, 1971; Lohiya *et al.*, 1999; Pathak *et al.*, 2000). It has hypoglycemic and hypolipidemic (Banerjee *et al.*, 2006; Adeneye and Olagunju, 2009), purgative (Akah *et al.*, 1997), antifertility (Bodharkar *et al.*, 1974; Das, 1980; Udor and Kehinde, 1999; Ekanem and Okoroinkwo, 2003; Ayotunde and Ofem, 2008), antibacterial (Eneruwa, 1982), Dengue virus suppressive (Nikkon *et al.*, 2003) activities.

M. oleifera reduce the risk of degenerative diseases (Paliwal *et al.*, 2011a) and is being used for the treatment of ascites, rheumatism (Anwar *et al.*, 2007), venomous bites (Mishra *et al.*, 2009), enhancing cardiac function (Limaye *et al.*, 1995), inflammation (Ezeamuzie *et al.*, 1996), liver disease (Rao and Misra, 1998), cancer, hematological, hepatic and renal function (Mazumder *et al.*, 1999), and heals cardiovascular, gastrointestinal, hematological and hepatorenal disorders (Paliwal *et al.*, 2011a). *Moringa* has been used in the traditional medicine passed down for centuries in many cultures around the world, for skin infections, anaemia, anxiety, asthma, blackheads, blood impurities, bronchitis, catarrh, chest congestion, cholera, conjunctivitis, cough, diarrhoea, eye and ear infections, fever, glandular, swelling, headaches, abnormal blood pressure, hysteria, pain in joints, pimples, psoriasis, respiratory disorders, scurvy, semen deficiency, sore throat, sprain, tuberculosis, for intestinal worms, lactation, diabetes and pregnancy (Nikkon *et al.*, 2003). The seed is often used to purify dirty or cloudy drinking water (Von Maydell, 1986; Gassenschmidt *et al.*, 1995; Katayon *et al.*, 2005; Kebreab *et al.*, 2005). It is also reported as anti-inflammatory (Caceres *et al.*, 1992; Rao and Misra, 1998), antimicrobial (Caseres *et al.*, 1991; Dahot, 1998; Jabeen *et al.*, 2008), antibacterial (Viera *et al.*, 2010), antioxidant (Fakurazi *et al.*, 2008; Paliwal *et al.*, 2011c), anticancer, antibiotic (Kurup and Rao, 1954), cardiovascular,

antispasmodic and antipyretic (Hukkeri *et al.*, 2006), hepatoprotective (Mazumder *et al.*, 1999), anti-ulcer (Akhtar and Ahmad, 1995), diuretic, antiurolithiatic, and anthelmintic by Farooq *et al.*, 2012.

M. sapientum has wound healing (Agarwal *et al.*, 2009) antidiarrheal (Emery *et al.*, 1997), antidiuretic (Jain *et al.*, 2007), antibacterial and antioxidant (Mokbel and Hashinaga, 2005), Hypoglycemic (Pari and Maheswari, 1999; Ojewole and Adewunmi, 2003; Singh *et al.*, 2007; Rai *et al.*, 2009), antihyperglycemic (Pari and Maheshwari, 2000) activities.

Thus, the target output of this investigation matches the hypothesis how these plants play role as bionormalizer causing 'no' or 'less' harm to the biodegrading agents, *i.e.* the bacteria. The diam. of the inhibition zones resulted in the antibacterial activity tests against the 9 isolates found in the tannery effluent were all within the range of 8 to 16mm for the size of the disc inoculated 6mm (included). It is obvious from the antibacterial activity tests that some of the bacteria found in the isolates were not affected by the extractives of the test plants, while some were responsive depicting very poor effect on them. These mildly active small molecules or secondary metabolites may be the components of the defense mechanism of the plants for their survival. Thus, it could be assumed that the bacteria which were survived the application of extracts may play an important role in degradation of the effluent making it gradually easy for the invasion of the other bacteria, as well as welcoming in near future the ones who were inhibited. The result of this investigation along with the outcome of certain other previous investigators suggest that 'among the components of the bionormalizer plants there are bioactive compounds, and those are effective against some of the biodegrading bacteria, but of course not against certain other members of the same group; thereby ensures survival of the plants working simultaneously besides the bacteria taking part in bionormalization'.

Analytical Report

Referred by : Dr. M. Sarwar Jahan
 Work Order details : Analysis report of the supplied samples (as supplied).
 Sample supplied by : Rukhsana Shalim, (Supervisor Dr. Md. Nurul Islam, RU)
 Type of Sample : Waste Water
 Quantity of sample : About 500 ml.
 Packing and Marking : Plastic Bottle.

Analytical Result:

| Sl. No. | Parameters | Results | | |
|---------|------------|-------------|-------------|--------------|
| | | S1 | S2 | S3 |
| 01 | pH | 7.24 | 7.29 | 8.74 |
| 02 | EC | 5.38mS/cm | 5.46mS/cm | 14.83 mS/cm |
| 03 | TDS | 2.69g/L | 2.73g/L | 7.41 g/L |
| 04 | Fluoride | 22.933ppm | 20.288ppm | 54.217 ppm |
